Chemical & Metallurgical Engineering

A Weekly Technical Newspaper,
Being the Incorporation of
Electrochemical and Metallurgical Industry
and Iron and Steel Magazine

Volume XXV

From July 1 to December 31, 1921

436850
3. 7. 45

NEW YORK
McGRAW-HILL COMPANY, INC.

GENERAL ALPHABETICAL INDEX

*Illustrated; (P), (B. P.)—United States and British patents respectively; (S.)—Synopsis; (N.)—Papers read at society meetings but not printed in full.

- Brazil:**
 —Electric iron and steel plant. Paulson 1057
 —Alcohol as locomotive fuel in 148
 —Few purchases of heavy chemicals in 528
 Brick, Cinder cement. To be tested 345
 Brick, Paving. Standardization of 892
 —Excess varieties eliminated 980
 British chemical industry.... 48, 269, 860, 1038
 British Columbia:
 —Paper plant reopens 528
 —To make steel from magnetite 716
 Bromine extraction and apparatus. Dow. (P.) 208
Bronze:
 —Schwartz furnace atmosphere when melting complex. Anderson and Capps 103
 Budget, Chemical items in 1113
BUREAU OF CHEMISTRY:
 —Directorship unattractive to many .. 169
 —Acting chief named 255
 —Appointment of chief delayed 525
 —Report of chief of bureau 1113
BUREAU OF MINES:
 —Alloy work discussed 980
 —Bureau of Mines to study light alloys. 625
 —Ceramic work being expanded 256
 —Chemical staff increased 1155
 —Co-operative agreements 761
 —Non-metallic investigations 527
 —Petroleum Experiment Station seeks technical men 123
 Bureau of Standards:
 —New standard samples 257
 Burns from calcium saccharate. Sherrill. 4
 Burton, William M., Perkin medalist ... 848
- C**
- Cadmium in 1920. Siebenthal and Stoll.. 29
 Cadmium-copper wire. Smith *1178
 Calcium carbonate:
 —Notes on metallurgy of. Brace *105
 Calcium acetate, Mfr. 238
 Calcium-barium-lead alloys. Electrolytic. Cowan, Simpkins and Hiers *1181
 Calcium bisulphate, Mfr. of. Richter. (P.) 208
 Calcium carbonate:
 —Forms of 149
 Calcium chloride solutions:
 —Vapor pressures of. Baker and Waite. *1174
 Calcium nitrate, Mfr. (B. P.) 340
 Camphor, Synthetic:
 —DuPont plant may resume 1156
 —Bernyl esters for (B. P.) 715
 Cam shafts, Tempering, Wandersee. (P.).. 208
CANADA:
 —Brass and copper industry 650
 —Business papers. Tribute to 1067
 —Ceramic school in Saskatoon 209
 —Chemical and allied industries. Statistics 822
 —Directory of chemical industries 672
 —Glass industry in 1918 115
 —Linseed oil in 1918 694
 —Soap industry statistics 506
 —Soap industry, 1918 751
 —Water-power resources 691
 Canadian Chicago Bridge & Iron Co. changes name 211
 Canis variegatus. Heterogeneity in. Seyt... 92
 Capital Increases, etc. 44, 87, 131, 176, 220, 264, 308, 352, 492, 579, 635, 679, 724, 768, 812, 855, 899, 944, 988, 1076, 1120, 1164, 1204
 Carbon:
 —Activation of. Ardagh. (N.) 500
CARBON BLACK:
 —From natural gas in 1920. Sievers. 333
 —Supreme Court decision on Wyoming industry. Dannerth 104
 —Ruling on 672
 Carbon monoxide, Catalytic oxidation of. Frazer. (N.) 1128
 Carboys. Regulations for transportation of. Carelessness. Wastes caused by. De Wolf. 433
 Casein cements, Mfr. of. (B. P.) 523
 Casein composition. (B. P.) 340
 Casein glues durable in damp places 607
 Cellulose:
 —Action of thiocyanates on. Clayton. (N.) 499
 Cellulose esters:
 —Solvents for. Willkie *1186
 Cellulose ethers:
 —Mfr. of. (B. P.) 340
 —Mfr. of. Dreyfus (B. P.) 714, 1021
 —Celluloid from. Dreyfus (B. P.) ... 715
 Cellulose Section, A. C. S.:
 —Fall meeting: 34
 —Plans 551
 —Report 551
CEMENT:
 —Potash recovery from cement kilns. Krarup *316
 —Chemical engineering needed. Dean.. 439
 —Wet process. Critical review of. Meade. (S.) 295
 —Foreign specifications 612
 —Foreign specifications charted 1020
 —Output increases in August 626
 —October output 1061
 —Philippine industry 735
 Census of Manufactures, 1919:
 —Preliminary summaries of 465
 Central Steel Co. Merger 717
CERAMICS:
 —Glimpses of Ohio ceramic industries. Jones I *562, II *619
 —Production wastes in. Minton 440
 —Ceramics as byproduct of coal mining in Sweden. Beckman 882
- CERAMICS—Continued:**
 —Bureau of Mines begins work on heavy clay products 77
 —Bureau of Mines ceramic work expanded 256
 —Ceramic engineering course at Illinois. 1112
 —Ceramic school at Univ. of Saskatchewan 209
 —Ceramic Station investigates burning. 527
 —Chemical stoneware: (see Acid-Resisting Materials).
 —Clay drying. New method 753
 —French porcelain industry. Growth of 124
 —Gas-fired kiln to be demonstrated .. 979
 —Laboratory car for brick kiln tests.. 978
 —Lead poisoning in pottery trade 78
 —Lecture course on burning of clay... 717
 —Pottery expositions being arranged.. 1067
 —Pottery products. Lower freight rates sought for 893
 —Pottery workers accept wage reduction 299
 Chamber of Commerce of the United States:
 —Natural resources reportment 893
 Charts:
 —Hamor's chart of aims of purposeful study of problems of chemical and physical technology *422
 —Measuring gases containing water vapor *329
 —Volumes of air required in air drying 1088
 Chemical and allied industrial markets... 38,
 81, 126, 170, 214, 258, 302, 346, 486,
 529, 573, 629, 673, 718, 762, 806, 850,
 894, 938, 982, 1026, 1070, 1114, 1158,
 1198.
 Chemical companies. New 212,
 299, 629, 805, 980, 1154
 Chemical engineering ideals. Wesson. (N.). 7
 Chemical industry:
 —Power and fuel data. Goodwin.... 708
 —Unemployment decreases in 716
 —Employment increases 1066
 Chemical market review 628
 Chemicals:
 —Waste due to lack of standardization. Cohoe 383
 —Census report for 1919 465
 —List of research chemicals in preparation 569, 892
 —Wholesale prices lower 672
 —Exports and imports:
 —May, 1921 37
 —Fiscal year 278
 —October 1069
 —Exports, Fiscal year 328
 Chemical stoneware: (see Acid-Resisting Materials).
 Chemical tonnage on railroads..... 77, 716
 Chemical warfare:
 —Alabama tests 626, 670
 —Consideration at disarmament conference 978, 1024, 1069, 1114
 —Weeks favors gas development..... 1113
 —Spread of war gases subject to control 1156
 —Anti-chemical propaganda rife..... 1193
CHEMICAL WARFARE SERVICE:
 —Moves offices 78
 —New proving ground ready..... 124
 —Service school course completed 124
 —Needs \$4,000,000 next year..... 213
 —Training plan outlined 298
 —Appropriation increased 1066
 —Survey shows gas leaves no permanent injury 1193
 Chemical welfare of America. Hendrick. (N.) 803
 Chemists' clubs exchange greetings..... 934
 Chicago Section, A. Cer. Soc.:
 —November meeting 1069
 Chicago Section, A. C. S.:
 —September meeting 670
 —October meeting 849
 —December meeting 1195
 Chicago's relation to future American steel industry. de Geer 325
 Chilean nitrate:
 —Declining importance of 717
 —New discoveries of 1185
 —Situation 1112
 China:
 —Vegetable tallow industry 522
 —Bibliography available 925
 Chlorine:
 —Electrolytic chlorine: caustic cells: Hooker. (P.) *1152
 Chlorine industry. Key position of. Brooks. (N.) 1127
 Chromium:
 —Electrolytic. (B. P.) 802
 Cincinnati needs river terminals..... 1157
 Civil service examinations 79,
 626, 670, 762, 1070, 1110
 Clay, Drying. New method 753
COAL:
 —Cleaning by use of oil. Trent process. Perrott and Kinney *182
 —Destructive distillation of mixtures of oil and. Davis, Place and Scott... *1131
 —Consumption by uses 648
 —Low-temperature carbonization. Beilby 228
 —Pulverized:
 —In iron and steel industry. Coffin.. *971
 —Volatile matter. Determination of. Wilkinson 925
 Coal ash. Fusing temperatures of coke ash and. Rose 141
 Coal tar:
 —Separating water from. (B. P.) *340
 Coconut oil:
 —Philippine exports of 323
 Coffee extracts, Mfr. of. Challas. (B. P.) 76
 Coke:
 —Coking mid-continent coals *710
 —Monthly statistical summary established 210
- COKE—Continued:**
 —Studies at Ohio State 571
 Coke ash, Fusing temperature of coal ash and. Rose 141
 Coke ovens:
 —Piette ovens to be introduced..... 342
 Colloids:
 —Colloid chemistry of petroleum. Padgett 189
 Color measurement in industry. Pfund. (N.) 849
 Colorado clays to be studied 1157
 Colorado Industrial Exposition 1069
 Commerce, Department of:
 —Annual report of secretary 1111
 —Additional commodity divisions 1112
 Concrete:
 —Use in construction of salt plants. (S.) 75
 Congress of Industrial Chemistry at Paris. 893
 Connecticut Valley Section, A. C. S.:
 —Officers elected 1025
 Construction and operation 43,
 86, 131, 175, 219, 263, 307, 351, 491,
 534, 578, 634, 678, 723, 767, 811, 855,
 899, 943, 987, 1031, 1075, 1119, 1163,
 1203.
 Construction wastes, Elimination of. Burpee 394
 Co-operation between University and industry. Johnston. (N.)..... 1195
COPPER:
 —Electrodeposition of alternate layers of nickel and. Blum and Slattery.. 320
 —Structure and properties of. Blum. 961
 —Electrolytic solution and deposition. Briggs. (N.) 689
 —Standards approved by A. E. S. C... 36
 Copper alloys:
 —Heat-treatment of. Isabellen Hütten Ges. (B. P.)..... 33
 Copper: aluminum alloys. Anderson. (N.). 688
 Copper-cadmium wire. Smith *1178
 Copper shingle production 759
 Copper sulphate:
 —Mfr. of pure. Mackay. (B. P.) ... 251
 Cordite, Artificial leather from 528
 Cores:
 —Air required in baking cores made with linseed oil. Grubb and Jamison 793
 —Comment. Olsen 948
 Cost methods:
 —Disclosing waste through better. Wessen 389
 Cottonseed products, Fundamental research program for 1067
 Cottrell precipitator: (see Electrical Precipitators).
 Crane, General purpose crawling tractor.. *712
 Crankshaft, Metallurgical examination of broken 14
 Credulochemistry. Comment. Frary 773
 Crushing:
 —Symposium at chemical exposition .. 587
 Crystal structure:
 —Studies with X-rays. Bain *657
 Crystallization. Impurities retard. Walton. (N.) 1025
 Current Events 34,
 77, 121, 165, 209, 253, 297, 341, 483,
 525, 569, 625, 670, 716, 759, 803, 847,
 892, 934, 978, 1022, 1066, 1109, 1154,
 1194.
 Cyanamide:
 —Electrolysis of. Kameyama. (N.).. 686
 Cyanure azide. Ott. (P.)..... 1192
 Czechoslovakia:
 —Radium production 1050
 —Restricts exports 934
- D**
- Dartmouth College dedicates Steele Chemistry Building 936
 Decolorizing carbon:
 —Mfr. DeBruyn. (B. P.) 296
 De-inking process. Chemical control of. Joyce 248
 Delaware Section, A. C. S.:
 —October meeting 849
 Dental amalgams. Gray. (N.)..... 1112
 Deoxidizers:
 —Alloys. Vos. (P.) 482
 Detinning processes:
 —Oleum. Mackay. (B. P.)..... 251
 Detonator, New. Ott. (P.) 1191
 Deutsche Chemische Gesellschaft:
 —November meeting 1156
 Dialkylaminoalkyl compounds. (B. P.)... 1064
 Diethyl sulphate, Properties. Curme 957
 Distillation:
 —Separating organic substances by. (B. P.) 1064
DRYING:
 —Air drying. Volumes of air required in. Mitchell *1088
 —Symposium at chemical exposition... 588
 —Air conditioning in. Lissauer. (N.).. 589
 —Atmospheric. Stern. (N.) 589
 —Moist air. Stonex. (N.)..... 588
 —Selection of driers. Landell. (N.)... 588
 —Vacuum. Chen. (N.) 589
 DuPont Fibersilk Co. plant in operation.. 36
 Dye Division, A. C. S.:
 —New York meeting:
 —Plans 168
 —Report 544
DYE LEGISLATION: (see also Tariff).
 —Investigation of dye industry demanded 121
 —Dye embargo eliminated as tariff passes House 165
 —Another Moses amendment 168
 —Dye vote surprises Congress 209
 —Dye embargo extended 297
- *Illustrated; (P.) (B. P.)—United States and British patents respectively; (S.)—Synopsis; (N.)—Papers read at society meetings but not printed in full.

INDEX

DYE LEGISLATION—Continued:

—Dye embargo argued at Senate hearings	297
—Senator Ladd's plea	342
—Joint dye committee named	344
—Extension of temporary dye control	345, 485
—Special duties continued	525
—Plea for protection, Hendrick, (N.)	803
—Dye and chemical control extended	805
—Dye investigation not ordered	1022
—Dye investigation ordered	1109
—Senate sub-committee appointed ..	1193

DYES:

—Is there an American dye monopoly? Breithut	*594
—Census of dyes and coal-tar chemicals, 1920	*166
—Natural dyes and extracts, Census report on	466
—Anthracene, (B. P.)	1021
—Germany advances prices	525
—Indigoid vat, (B. P.)	933
—Industry lacks business knowledge ..	434
—Monoazo, Morgan, (B. P.)	33
—(B. P.)	933
—National Lime Association urges protection	123

E

Earthenware, Embossed, Reduced duty for ..	717
Edible oils:	
—Basic technical information needed, Ingram	438

EDITORIAL:

—Act! but think first	726
—Administrative and business opinions on tariff policy	1077
—Agricultural support for the chemical industry	901
—Alcohol dyes and industrial supremacy ..	221
—And again, what is a chemist?	451
—And now the question: "What is the chemical engineer?"	683

EDUCATION:

—Educational waste in industry, God-frey	378
—Training glass works chemist, Silver-man	332
—Metallurgical, Notable movement in, Comment, Gilligan	993
—Culture in technical education, Com-ment, Hart	452
Elastic limit, Dalby (S.)	*623

ELECTRIC FURNACES:

—For silver, gold and metals of low melting point, Herlenius	*455
—Arc and resistance, Rennerfelt, (B. P.)	*669
—Baily furnace, Baily, (N.)	687
—Electrode arrangement, (B. P.)	296
—Glass-annealing lehrs, Collins	119

ELECTRIC FURNACES—Continued:

—Internal resistance type, (B. P.)	*73
—Muffled arc type, Wunne, (N.)	655
—Rebel Arc furnace	*1109
—Resistance type for sheet heating	*567
—Resistance type for steel melting	*667
—Turret furnace for heat treating	*713
—Vitreous enamel furnace	*296
Electric heating directory planned	844
Electric power stations shown on new series of maps	1014

ELECTRICAL PRECIPITATORS:

—Eliminating smoke, fume and gas nuisances and wastes with, (Land-olt)	*425
—Installation at Santa Cruz Portland Cement Co.	*318
—Use for separating fog in wood gas ..	195
—Process, Welch, (P.)	*670
Electrochemical developments auxiliary to hydro electric plants, Benson	1004
Electrochemical products:	
—Power requirements and cost, Seele, (S.)	32

Electrodeposition:

—A. E. S. symposium	659
Electrolytic cell, Williams, (P.)	298
Electrolytic processes, Graphic control, Worth, (N.)	657
Electrometallurgy, Non-ferrous:	
—A. E. S. symposium	657
Elyria Enamelled Products Co. plant, Jones ..	*927
—Research Laboratory, Poste	*974

Emulsions:

—Petroleum, Padgett	189
---------------------------	-----

ENAMELED EQUIPMENT:

—Enamelled steel manufacture, Jones	*853
—Enamel-lined apparatus, Jones	*927
—Enamelled products research labora-tory, Poste	*974
—Uses for industrial enamelled equip-ment, Donauer	*1015

Enamels:

—Electric furnace for vitreous enamels ..	*206
—Fish scaling of, Co-operative factory investigation	123
Energy, Source and future of, Little, (N.)	542
Engineering societies' delegates, Dinner to ..	739

ENGLAND:

—Ammonium sulphate embargo lifted	572
—British chemical industry, 48,269,860, 1038	
—British chemical workers to strike	343
—Dispute settled	527
—Brunner Mond dividend	1067
—Chemical imports affected by act	484
—Denatured alcohol plan	1025
—Disposal of government surplus chemicals	847
—Labor disputes and wage reductions in chemical plants	483
—Steel-works practice, Coulson, (S.)	1190

Ethyl acetate:

—Anhydrous, Properties of	1186
---------------------------------	------

Ethylene:

—Sources and uses, Curme	907
Ethylene chlorhydrin, Properties, Curme and Young	1091
Ethylene dichloride, Properties, Curme ..	999
Ethylene oxide, Properties, Curme and Young	1091

EVAPORATION:

—Studies in evaporator design, V Badger	*459
—Multiple effect evaporation, Dung-linson	*110
—Comment, Mellor	453
—Vapor compression, Dunglinson	*246
—Regenerative or vapor compression, Badger, (N.)	1129
—Symposium at chemical exposition ..	588
—Criss-Cross evaporator, Cook, (N.)	*589
—Enamelled evaporators, Donauer, (N.) ..	588
—Evaporation, Austin, (N.)	589

Explosions:

—Use of inert gas for prevention of, White	*513
—Comment, Bell	729
Extensometer calibrating device, Templin ..	*248

F

Fats:

—Statistics, Fats and oils, First quar-ter, 1921	148
--	-----

Fatty Acids:

—Distillation plants, Operation of, Wurster	*651
—Mfr. of triglycerides of, (B. P.)	*524
—Polymerizing, (B. P.)	1021

Federal Power Commission:

—First report	1110
---------------------	------

Federal Trade Commission:

—Issues order against Royal Baking Powder Co.	211
—Gypsum Industries' Association cited ..	570
—Procter & Gamble Co. cited	1025
—Complaint against Steel Corporation amended	1111

Federated American Engineering Societies:

—Dean Cooley discusses problems fac-ing	847
—To review progress at annual meeting ..	1023

Fermentation process, Continuous, (B. P.)

Fertilizer Division, A. C. S.:

—New York meeting, Report	605
---------------------------------	-----

FERTILIZERS:

—Science and the coming agriculture, MacDowell	785
—Census report for 1919	466
—Farmers to demand free	571
—Freight rates discussed	892
—Hungarians organize company	528

- FERTILIZER—Continued:**
 —Movement during fiscal year..... 526
 —National Fertilizer Association co-
 operating with Bureau of Census... 484
 —Peninsula manufacturers organize... 1157
 —Sweden lifts export embargo..... 670
Filters:
 —Filter press, Improved type of. Bur-
 chenal..... *476
 —A. C. S. symposium. (N.)..... 545
**Fireproof protection of extra-hazardous
 risks in manufactories.** Patterson... *887
Fire waste, Some considerations of. Rich-
 ardson..... 397
**Fixed Nitrogen Research Laboratory (see under
 Nitrogen Fixation)**
**Foch made honorary member of engineering
 societies**..... 1153
Food-preservation industries:
 —Technically trained men needed.
 Cruess..... 435
Food products:
 —Industrial waste of..... 435
Forest Products Laboratory:
 —Plans for 1921-22..... *27
 —Wood Waste Exchange transferred to
 123
Formaldehyde, Mfr. of. Bailey. (P.)... 668
FRANCE:
 —American Field Service Fellowships for
 French Universities..... 892
 —Beet-sugar industry in northern
 France..... 188
 —Coal production in devastated regions
 792
 —Congress of Industrial Chemistry at
 Paris..... 893
 —Foreign trade in first four months,
 1921..... 152
 —Industrial reconstruction of devas-
 tated region..... 1101
 —Porcelain industry, Growth of..... 124
 —Reforestation of..... 1014
 —Sugar production, 1920-21 season... 148
Fray metal, Electrolytic. Cowan, Simp-
 kins and Hiers..... *1181
Freight movement increases...... 671
**Fritz medal for 1922 presented to Eugene
 Schneider**..... 121
Fuel gases, Purifying. Ramsburg. (P.)... 1191
Fuels:
 —A. C. S. symposium..... 546
 —Fuel and power data, Chemical in-
 dustry. Goodwin..... 708
 —Selection for industrial heating..... *116
Fuller's earth:
 —Production, 1920..... 16
Fumigation with HCN, Safeguarding...... 1155
**Furfural, Condensation with aniline in
 water.** Montgomery and Ernst..... 335
G
Gas and Gases:
 —Blast-furnace, Design of cleaners for.
 Gellert..... 287
 —Inert gas, Use in prevention of explo-
 sions. White..... *513
 —Comment. Bell..... 729
 —Measuring gases containing water
 vapor. Estep..... *329
 —A. C. S. symposium. (N.)..... 546
 —Census report for 1919..... 467
 —Combustion of gaseous fuels. Grebel.
 (S.)..... 75
 —Rare. Moureu. (N.)..... 1197
 —Complete gasification process. (B.
 P.)..... *339
 —Flow of, Device for measuring. Re-
 ply to comment. Hayward..... 5
 —Fuel gases, Purifying. Ramsburg.
 (P.)..... 1191
 —Medicinal properties to be studied... 804
 —Statistics on development of industry
 916
Gas analysis:
 —Apparatus for. (B. P.)..... *33
Gas mask for ammonia approved...... 125
Gas purification:
 —Process. (B. P.)..... 715
GASOLINE:
 —Peat process:
 —Court demonstration fails..... 1109
 —Declared fraud..... 1154
 —Quality of motor gasoline..... 324
 —Vapor pressure..... *752
Gelatin:
 —Data wanted on..... 77
 —Vegetable gelatine, Mfr. of. (B. P.)
 76
Genclite, a new bearing metal..... *207
General Bakedite Co. wins patent suit.
 Georgia, Industrial conditions improve in.
 Georgia white clays and bauxites to be
 studied..... 672
GERMANY:
 —Oppan disaster:
 —Cause..... 672
 —Further data..... 760
 —Impressions of and comments on.
 Comment. Kendall..... *818
 —B. A. S. F. to resume nitrogen fixation
 849
 —Chemical industry, Developments in... 163
 —Chemical industries in..... 1189
 —Dye prices advance..... 525
 —Explosion in salt-peter works..... 670
 —Fertilizer syndicate to market ammo-
 nia..... 935
 —Foreign trade in 1920..... 888
 —Kalisyndikat officials to visit U. S... 345
 —Labor situation..... 1196
 —Labor troubles in chemical industry.
 Leather industry, Status..... 914
 —Plants close down..... 671
 —Potash sales..... 278
 —Potash statistics..... 828
 —Taxation of American enterprises in... 828
 —Trade with Santiago de Cuba..... 656
 —Wages in metal industry..... 160
**Gilchrist, Colonel Harry L., receives D. S.
 M.**..... 124
GLASS:
 —As construction material in chemical
 industry. Marshall. (N.)..... 1128
 —Heat-intercepting. Alleman. (N.)... 499
 —Lehrs, Electrically heated. Collins... *119
 —Training glass-works chemist. Silver-
 man..... 332
 —Waste in. Tillotson..... 437
 —Belgian plate-glass costs..... 618
 —Canadian industry in 1918..... 115
 —Improved conditions..... 671
 —Operations in West Virginia..... 528
 —Research to be done on..... 672
 —Standardization conference..... 805
 —Wage reduction..... 527
GLUE:
 —Wastes in glue industry:
 —Causes of. Bogue..... 443
 —Efforts to eliminate. Tennant... 443
 —Casein glues durable in damp places.
 Data wanted on..... 607
 —Use of magnesium carbonate in... 77
 —Glue stains, Removal of..... 508
 Glycerine..... 241
 —Alcoholic fermentation as source of.
 Schweizer. (S.)..... 891
 —Fermentation process. (B. P.)..... 669
Gold:
 —Melting in electric furnaces..... *457
 Grease, waste, distilling. (B. P.)... *524
 Greensand as source of potash. Shreve... 1056
Grinding:
 —Economy of modern methods. Hard-
 inge..... 229
 —Symposium at chemical exposition... 587
**Gypsum Industries' Association cited for
 unfair competition**..... 570
H
Hardwood distillation (see Wood distillation)
HELIUM:
 —Petrolia plant shut down..... 212
 —Government to study..... 525
 —Successful flight with..... 1068
 —Practical use demonstrated..... *1111
 Hexane, Vapor pressure..... *752
**Highway engineering, Chemical engineer
 and.** Blanchard. (N.)..... 8
Humidity table for psychrometer readings.
 Hydrocarbons..... 746
 —Pyrolysis of. Denig..... *751
 —Halogenating. Loomis. (P.)..... 668
Hydrochloric Acid:
 —Electrolytic oxidation to perchloric
 acid. Goodwin and Walker..... 1093
 —New salt cake and hydrochloric acid
 furnace. Laury..... *834
 —Use by industries during war. Bailey.
 (S.)..... 481
**Hydro-electric inspection by Buffalo engi-
 neers**..... 629
Hydrogenation:
 —Catalyst for. Bolton. (B. P.)..... 296
Hydrogen-ion concentration:
 —In natural waters. Wolman and Han-
 nan..... *502
 —Practical applications of electrometric
 control. Klopsteg. (N.)..... 876
Hydrogen peroxide, Pure, Properties of.
 Maass. (N.)..... 499
Hydrolysis of salts, Gradual. Tian. (S.)
 32
Hygrometer, Care and use of...... 192
I
India:
 —Chemical research in. Watson. (S.) 338
 —Lac tax..... 526
 —Leather industry in. Ledgard..... 481
**Industrial and Engineering Chemistry Divi-
 sion, A. C. S.:**
 —New York meeting..... 545
Industrial Cost Association:
 —Pittsburgh meeting:
 —Program..... 804
 —Report..... 935
Industrial management:
 —Symposium at Industrial Relations
 Association..... 959
Industrial notes,
 44, 87, 352, 536, 635, 900, 944, 1076,
 1164, 1204
Industrial relations:
 —Pennsylvania conference..... 77
Industrial Relations Association:
 —New York meeting:
 —Program..... 625
 —Report..... 959
Industrial safety:
 —Engineer's part in. Tolman..... 203
**Insecticide and Disinfectant Manufacturers'
 Association:**
 —Atlantic City meeting..... 36
Institut de Beauté, Oxygen research at.
 Seyt..... 224
Internal Revenue:
 —Collections..... 528
 —Work of chemical division..... 1197
International Labor Conference:
 —Discusses white lead and anthrax... 980
 —To adopt convention on..... 1024
**International Union of Pure and Applied
 Chemistry:**
 —Brussels meeting:
 —Report..... 344
Interstate Commerce Commission:
 —Dates set for rate reduction argu-
 ments..... 1193
 —Inventors are active..... 224
Iodine:
 —Chilean industry..... 788
 —Iowa University of:
 —New chemistry building for..... 956
Iron:
 —Solid solutions of oxygen in. Stead
 and Whiteley. (N.)..... *960
 —Electrodeposition of. Hughes. (N.) 689
 —Electrolytic. (B. P.)..... 802
 —Electrolytic cleaning process. (B. P.) 296
IRON AND STEEL:
 —Analysis:
 —Sulphur in malleable cast iron.
 Crome..... 247
 —Corrosion (see Metal protection and
 corrosion)
 —Defects:
 —Internal service-strains in steel.
 Howard..... 275
 —Fatigue under repeated stress..... *1141
 —Effects of surface scratches. Coker.
 (S.)..... 714
 —Squaring a circle. Patterson... *1063
Effect of Various Elements:
 —Nitrogen in carburized steels.
 Ruder and Brophy..... *867
 —Comment..... 1036
 —Sulphur in malleable cast iron.
 Crome..... 247
Foundry Practice:
 —British view on steel foundry fur-
 naces..... 755
Furnaces:
 —Causes of high top heat in blast
 furnace. Imhoff..... 737
 —Heat balance of a blast-furnace
 stove. Wilson..... 200
 —Open-hearth ports. Kagarise. (N.) 952
 —Resistance type furnace tested... *667
 —Turret furnace for heat-treating... *712
General:
 —Chicago's relation to future Amer-
 ican steel industry. de Geer... 325
 —Pulverized coal in. Coffin..... *971
 —Surface of liquid steel. Johns.
 (S.)..... 714
 —Composite articles of iron and
 steel. Longmuir. (S.)..... 1108
 —Pig iron, Census report for 1919... 470
 —British steel-works practice. Coul-
 son. (S.)..... 1190
 —Independent steel merger contem-
 plated..... 1069
 —Proposed Western merger..... 1068
 —Industry at Buffalo resuming... 528
 —Imports from Europe..... 970
 —Italian production..... 822
 —Japanese production..... 515
 —Swedish industry..... 952
Heat Treatment:
 —Artificial seasoning of steels.
 French..... 155
 —Equilibrium between iron, carbon
 and oxygen. Comment. Giolitti... *312
 —Hardening high-speed steel. Vari-
 ous methods. d'Arcambal... 1150
 —Hardness of high-speed steel. d'Ar-
 cambal..... *1168
 —Influence of mass in. Janitzky... *783
 —Of high-speed steel cutting tools of
 intricate design. Langhammer... *30
 —Oxidation of carbon tool steel on
 heating in air. Scott..... *72
 —Case-hardening. Aitchison. (S.)... 164
 —Hardening tool steel. Brayshaw.
 (S.)..... 891
 —A. S. T. M. committee notes on... 14
 —Case-hardening symposium, A. S.
 S. T. 642
 —Hardening tool steel, A. S. S. T.
 papers. (N.)..... 645
 —Heat treatment of ordnance. (N.) 644
 —Regenerative furnace for..... 800
 —Turret furnace for..... *712
 —Hardening tools. Tate. (B. P.)... 33
Ingots:
 —Sound ingots and rails as a matter
 of course. Hadfield..... *772
 —Comment. Gathmann..... 1080
 —Gas-free ingots..... 1024
Metallography (see also Heat treatment):
 —Constitution of martensite and
 troostite. McAdam..... *613
 —Contrast etching. Rawdon and
 Lorentz..... *915
 —Electrolytic etching. Improved.
 Velguth..... *567
 —Etching agent for chromium and
 tungsten steels. Daevs. (S.)... 1151
 —Macroscopic examination..... 334
 —Microscopic examination..... 471
**Physical Properties (see also Heat treat-
 ment):**
 —Endurance under repeated stresses.
 McAdam..... *1081
 —Hardness variations in heat-treated
 steel. Hayward..... 695
 —Comment. Woodward. Reply.
 Hayward..... 905
 —Impact properties of various steels.
 Langenberg..... *910
 —Internal service-strains in steel.
 Howard..... 275
 —Fatigue under repeated stress..... *1141
 —Instrument to measure elongation
 of broken tensile specimens.
 Woodward..... *756
 —Elastic limit. Dalby. (S.)..... *623
 —Elastic properties after overstrain.
 Greaves. (S.)..... 667
 —Impact strength of carbon steel... 163
Processes:
 —Basset process. (S.)..... 568
 —Bessemer:
 —Spectroscopic examination of
 converter flame. Campbell... 618
 —Direct process for steel. Bour-
 coud. (N.)..... 951
 —Electric pig:
 —Electric reduction of iron ores.
 deFries..... 193

*Illustrated; (P), (B. P.)—United States and British patents respectively; (S.)—Synopsis;
 (N.)—Papers read at society meetings but not printed in full.

IRON AND STEEL—Continued:

Brazilian electric iron and steel plant. Paulsson	1057
Electric smelting. Hodson.....	881
Electric steel:	
Brazilian electric iron and steel plant. Paulsson	1057
Open hearth:	
Recarburizing. (B. P.)	340
Pig iron:	
Action of titanium in blast-furnace slags. (S.).....	801
Process. (B. P.).....	669
Desulphurizing. Koppers. (B. P.)..	296
Special Steels:	
Chromium steels:	
Bibliography and abstracts. Zimmerli	837
Etching reagent for. Daevs. (S.)	1151
Haber ammonia process steel. French. (N.)	647
High-speed steel:	
American manufacturing practice. d'Arcambal	1097
Hardening. Various methods. d'Arcambal	1150
Hardness of. d'Arcambal.....	1168

By Wellington Gustin.	
Chemical company obtains reversal of decree under workmen's compensation act in Maine	160
Churchward patents held no invention—Prior art and history of vanadium alloys	159

LEGAL NOTES—Continued:

Company held not responsible for injury to employee by explosion in gas pipe line	68
Condition in offer prevents contract agreement	796
The Conrad patents, the noiseless gear, using Bakelite mica, void for lack of invention	795
Cyanide pond owners liable for death of live stock	464
The Gaulin patent, Claim 7, held valid, but not infringed	1054
George patent for cooling bed held an advance in art and valid.....	321
Laboratory tests cannot outweigh the test of practical use	926
Nitric acid with sulphuric acid added to prevent corrosion not subject to duty	461
Non-delivery under installment contract not justified by non-payment for past delivery	31
Nuisance in storage of crude petroleum	464
Only attempt to sell goods as another's is unfair competition.....	69
Pearse patent held anticipated and void by District Court	872
Sale of goods before organization of company	872
Tank agitation patent held invalid as not being invention	926
Trader may announce in advance circumstances under which he will refuse to sell.....	872
Utzma patents for gypsum plaster board held valid	512
When mechanical equipment does and when it does not become fixtures..	31
Lehigh Valley Section, A. C. S.:	
September meeting.....	670
Officers elected	1157
Lenses, Microscope	115
Libraries, Special, Directory of.....	909
Lighting, Poor, Elimination of waste due to. Harrison	407
Lightning. Acid tank struck by. Wolf... 336	
Lignite:	
Briquetting. Thomson. (N.)	500
LIME:	
Dependence of lime industry upon nature and science. Little	149
Fine art of lime burning. Wood	705
Available lime in quicklime and hydrated lime. Whitson	740
Separation from dolomite. Schurecht. (S.)	891
Linseed oil:	
Canadian industry, 1918	694
Boiling with electric heat	844
Lithium minerals in 1920	21
Lithopone:	
Production costs	1196
Sales in 1920	346
Litigation wastes. Gustin	423
Location as a factor in eliminating waste.	
Kelsey	401

Status of chemists in	981

New Companies.	
44, 87, 131, 176, 220, 264, 308, 352, 492, 535, 579, 635, 679, 724, 767, 811, 856, 900, 944, 988, 1032, 1076, 1120, 1164, 1204.	
New Jersey Chemical Society:	
—October meeting	760
New Jersey Clayworkers Association:	
—To hold annual meeting	1024
—Report	*1194
NICKEL:	
—Latent heat of fusion of. White ..	*17
—Electrodeposition of alternate layers of copper and. Blum and Slattery.	320
—Structure and properties of. Blum.	*961
—Concentrated HCl etching reagent for. Rawdon and Lorentz	*955
Nickel-chromium alloys:	
—In heat-treating furnaces. Gatward. (N.)	10
Nickel silver. Physical tests on sheet. Price and Davidson	*141
—Electric melting. Thompson. (N.) ..	688
Nitrocellulose:	
—Chemistry, mfr. and uses. Schlatter.	*281
NITRIC ACID:	
—Superconcentration of. Galle	*741
—Distillation studies of nitric acid and sulphuric-nitric mixtures. Pascal. I.	*1103
II.	*1145
NITROGEN FIXATION:	
—European developments	299
—Fixed Nitrogen Research Laboratory:	
—Transferred to Dept. of Agriculture	167
—Government plants:	
—Ford offers to buy	124
—Hoover comments on Ford's offer ..	168
—Muscle Shoals on tapis again	209
—Muscle Shoals situation	342
—Ford invited to Washington	526
—Another Muscle Shoals offer	625
—Confer on Muscle Shoals	849
—Weeks and Ford to confer	936
—Deal likely to go through	1023
—Ford and Edison inspect	1069
—Supplement to Nitrogen Products report. (S.)	568
—Synthetic ammonia: (see under Ammonia)	
Nitrogen Products Committee report supplement. (S.)	568
Nitrogen purifying equipment	*74
Nitroglycerine:	
—Manufacture of. Symmes	*831
Nitrostarch explosives. Snelling. (P.) ..	846
Nitrous gases:	
—Absorption by sulphuric acid. Sanfourche. (S.)	623
—Absorption of. (B. P.)	*482
—Drying and liquefying. (B. P.) ..	802
—Separating from mixtures. (B. P.) ..	933

Number 1

Long-Time Forest Policy

THE paper industry in the United States, covering as it does paper board, newsprint, book, wrapping and many other grades of product, represents a tremendous output both in tonnage and value. A very large percentage of this chemical industry is dependent upon wood-pulp supply as its raw material, and as a consequence is vitally concerned in the forest policy which the nation may adopt. It is estimated that the paper industry uses five and one-half million cords of wood a year, the equivalent of forty to eighty years' growth of timber on a half million acres of forest land. It is easy to see, therefore, why a long-time policy rather than any year-to-year planning is essential.

In this planning three major points require consideration: First, the problem of efficient utilization of the forests which are cut; second, the protection of forests against wasteful attack, either by commercial depredation or forest fire; and third, a reforestation policy that is adequate to the national need.

In many parts of the country there are today lumbering activities which from the chemical point of view are most wasteful. For example, in the neighborhood of Puget Sound the Forest Service believes that the cutting of lumber is accompanied by the waste of much more than enough pulp wood not useful for lumber than would be required for the supply of several good sized pulp mills. If in this territory market for this pulp wood were created by establishment of a modern mill, of say 100 tons per day capacity, it seems certain that more than an adequate supply of wood would be offered at once. This material would come from the forests being cut for lumbering operations where a considerable percentage of the trees is now wasted because they are unsuitable for the local lumber markets, though they are well suited to pulp production if such market were available.

In many other parts of the West there are other possibilities in development of chemical industry for pulp-wood production that are most attractive. For example, in the neighborhood of the forest reserves under the control of the Forest Service the investment for paper production is most effectively minimized by the generous plan which the Forest Service offers to any who require this type of forest supply. Under this scheme it is necessary only to make a deposit on a contract for pulp wood to permit extensive cutting. These deposits are usually \$10,000 each, which will allow cutting to any extent permitted under proper forester control up to the total of the deposit and at any rate that may suit the need of the purchaser. When the first deposit is thus used up it is necessary only to make a second deposit on the contract and thus continue

over a period of years with ample forest reserve assured at a minimum capital investment. Of course in any of these cases the economic factors of the situation must be considered in order to insure commercial success, but the prospects seem most attractive in many circumstances.

The destruction of forests by fire in the territory nearer paper markets is even more alarming than the waste of pulp wood in the West. It is estimated by the Forest Service that these losses amount to over four million acres valued in excess of thirty million dollars per year. The consequence of these forest losses upon the cost of pulp wood and paper is obvious. Adequate protection by co-operation of state and federal authorities is of greatest importance to the industry.

There are also many problems of permanence in this industry which are dependent upon reforestation and maintenance of national forests. These are the problems which require vision for long-time development, but they are just as vital to permanence of investment and adequacy of future supply as any of the others. It is high time that the chemical industries involved should concern themselves with these problems from a chemical point of view, for they have chemical need as well as broad economic significance.

The Permanent Tariff Revision

TARIFF legislation, difficult to frame even under normal conditions, has been complicated by many unusual factors. The domestic industry, suffering under severe depression, asked not only for the restriction of foreign competition, but for legislation which it thought would assist it in recovering and expanding our export trade. Our change from a debtor to a creditor nation and the tremendous obligations of foreign countries which can only be repaid with goods have resulted in an uncertain and unsettled international situation. The measure for the revision of the permanent tariff, which has just been reported by the Ways and Means Committee, must be regarded, therefore, only as the initial attempt at the solution of an extremely perplexing problem.

It is difficult to compare the new bill with former tariff legislation. It has been framed to meet an entirely different situation and it is only natural that its framers have been forced to resort to many new and unusual provisions. Home valuation, retaliatory duties, anti-dumping, and the principles of the bartering tariff, although more or less foreign to our customs practice, have apparently been warranted by the specific conditions confronting our industries.

The chemical schedule of the new bill, which has been given detailed study on other pages of this issue, also

contributes its share of innovations. The special protection demanded by the dye industry has resulted in the proposal of a new form of control, which presumably is calculated to meet the growing opposition to the original licensing scheme. Likewise, potash and the other so-called war minerals have called for unusual treatment.

The reporting of the new bill marks the opening engagement of the impending tariff battle, the outcome of which will be awarded with anxious concern. Rumors are already afloat to the effect that opposing elements are dissatisfied with many of the provisions and that new schedules will have to be written or new compromises effected. The metal schedule particularly was the subject of violent criticism as soon as its contents became known. The entire bill will necessarily be modified before it leaves the House, some of its provisions will be rewritten in the Senate, and, finally, the last minute changes will be made in conference.

Need of Better

Association Machinery

WHEN necessary to increase plant production a manager usually has the choice of installing more machines or removing the present equipment and putting in better machines. In technical association affairs we are nationally in just that situation today. And, unquestionably, *better* association methods and machinery are needed.

Recently in Washington a conference of engineering society representatives considered the problem of some sort of engineering association and engineering club. At once two problems arose: First, how to get cooperation and efficient working together, and, second, how to avoid neglect of the specialties within chemistry and engineering that fully justify separate associations or institutions.

Almost everyone can recall from pre-war days the old association "table of equivalents" jokingly cited in reference to German technical society affairs. This started out by making two persons an association, three associations a federation and so on up until the entire universe was affiliated. This reference to the system, which we might call "a much-machinery system," points clearly to the evil of creating a new organization or club every time there is some rather new function to perform. The result obviously is only more wheels and charts of relationships, all of which consume much time and energy and give but little in compensating results.

For local affiliations such as proposed in Washington there is one scheme which really has worked. This provides a local office with a secretary from which are sent out common notices to the mailing list of all the affiliated bodies. Thus all members of all societies are reached regularly with notice of every activity in which they may be interested. It is to be hoped that some similar scheme may be evolved for Washington and that it will succeed as well there as it has in Cleveland, Buffalo and elsewhere. In fact it is to be hoped that Washington will add new variations or create a new scheme of this sort that is even better than those yet reached. Engineers and chemists are much too busy persons to welcome more societies or more affiliations of societies if they do not replace rather than supplement the present. Better association machinery is certainly all we need, not more associations.

Other Views on

The Mineral Tariffs

MARC PAWL'S article on the mineral tariffs has elicited some comments from our readers, which we are pleased to print on another page of this issue. At the outset, however, we must admit that we are disappointed because our correspondents have, for the most part, ignored the broader questions of conservation and national policy and have confined their views to the purely tariff issues presented by the individual minerals in which they are interested. We are glad to learn, for instance, that with scientific methods our crucible makers can use Alabama graphite to better advantage than the Ceylonese product, although this does not exactly confirm the reported experience of the twelve manufacturers who opposed the tariff on graphite at the hearings last February. "Searles Lake would keep us going at the present rate of consumption [of potash] for 75 or 100 years and doubtless by that time our chemists will be making potash out of soda." We don't want to discourage our potash alchemists, but might they not better divert their energy toward finding a cheaper means of transporting the Searles Lake product to its South Atlantic market?

But all that this proves is that the tariff still is, and probably always will be, a fruitful source of controversy.

Expecting Arrest

Or Protection?

ONE of our most prominent citizens recently remarked that industry long has regarded the Government as a policeman rather than as a friend. No doubt much of industry has taken this attitude—to what extent because it had a guilty conscience is worth considering.

If you drive your automobile up to a street intersection at forty-five miles per hour, which is above speed limits even in New York City and Los Angeles, our two coast cities of greatest speed and size, what would you expect of the officer at the "Stop-Go" semaphore? For our part we should expect that you would get a summons in next day's mail, if you were not more promptly invited to join an officer in a ride to the nearest precinct station. On the other hand, driving up with the car under control, with cut-out closed and if necessary making a stop before reaching the sidewalk line, you properly expect, and you get, a courteous signal from the officer for a *protected* crossing of the intersecting street.

The Secretary of Commerce is calling group conferences from industry to meet with him and his principal assistants to discuss statistics, standardization and simplification, and other basic matters of commerce and industry. It is a question how he shall be approached by industrial representatives. It is economic traffic which he desires to protect and direct; and the economics of this traffic, therefore, must be considered.

Chemicals, iron and steel, non-ferrous metals, rubber, textiles and all the other groups of products from chemically-controlled industry will in time receive attention. If they approach the crossing within the economic speed limit, they will obtain from the worthy Secretary and the capable associates whom he is gathering about him economic signals invaluable to their traffic movement. It is not a blustering, red-faced, bull-necked officer that they are to deal with. It is a courteous guard of business movement who knows more in many cases than industry itself about how each part of industry should move for-

the safety and speed of all. An approach in this spirit by industry will facilitate getting of much-needed governmental advice.

The comparison must not be pressed too far, however. If we disobey the traffic officer at the corner, more than likely we shall be "pinched." Almost certainly the least we get is a publicly administered reproof. In dealing with the Department of Commerce, however, it will be only advice and guidance of the most friendly sort that will be furnished. The decision as to whether industry will "stop" or "go" will remain with the business executive, where it belongs under our system of government. On behalf of the Department of Commerce therefore, and in the interest of business itself, let us hope for and insist upon a relationship of co-operation; and let us put aside fear of the Government, the old-fashioned bogey of our national industrial childhood. Certainly it would seem that industry had long since outgrown it.

The Return of Industrial Activity

IT IS quite clear that for a return of industrial activity we require something more than removal of the causes that produced the depression. Roughly speaking, the case is analogous to a patient suffering from a germ disease. Complete recovery does not instantly follow disappearance of the germs. The patient must convalesce, or get over the results of the disease. On this account we must not pin too much faith to "deflation" or insist that when certain commodity prices have come down others must come down by similar amounts before business can be ready to go forward.

Perhaps, indeed, we have been a little too critical about prices. The idea is right, but almost anything can be carried too far. Some months ago a common thought was that prices would have to get down to a certain relation to pre-war levels, the chief question being what that relation should be. As certain commodities declined we were disposed to take them as standard and expect other commodities to do likewise. No longer can we hold to any such doctrine. There is zinc, for instance. It is not down to its pre-war average. It is 8 per cent below its lowest in the five years before the war.

Nor can we follow what might be called a corollary to the theory that price deflation by itself will remove the industrial depression, that the commodities that first get down to the proper price level will first become active, for in many cases it is an especially light demand that has forced one commodity or another to a particularly low price, relative to the general average.

Now that we have before us recovery from the influences of depression as well as from the causes of depression, demand or activity is not going to revive by commodities, but rather by classes of consumption. To illustrate concretely, both nails and lumber are used in dwelling house construction and in making boxes for the shipments of a wide variety of merchandise. If lumber came down and nails stayed up, we ought not to expect the demand for lumber to become heavy, with the demand for nails remaining light.

Throughout the country there has been underbuying for months. No doubt this started by "a strike of buyers," but it has gone beyond a voluntary act, for with so much unemployment and so much reduction in wages and salaries the power to buy has been greatly reduced. Few can now buy what they would like to have. What people will buy first will be the things they need most and, to an extent, what they think are the better invest-

ments, preference being given where possible to commodities that seem the cheapest. The things that wear out the most rapidly or are most useful will experience the first revival in demand.

Obviously the beginning of industrial revival will not be in construction work. That is something that can most readily be postponed. The common everyday commodities, things that have only a short life at best, will be bought first. Then there will be more employment, increased buying power and a further increase in buying. The steel industry, for instance, which is now running at 20 per cent or less of capacity, or at a lower rate than is necessary merely to take care of the country's wear and tear, will find its first revival in demand not in steel for construction work, but in steel for restoring the wear and tear on railroads, the replacement of tools and agricultural implements, and in channels of that general description. The most unlikely thing is that industrial revival will begin with a "building boom."

Talking in Large Figures

IN 1914 the Census of Manufactures reported the total value of manufactured products as 24 billion dollars. The preliminary summary of the 1919 census gives a corresponding figure for all industries of 60 billion dollars, an increase to 250 per cent of the previous value. These numbers are rather too big to digest as a whole, and therefore it is worth while to pick them to pieces and see what they really mean.

It would not be at all reasonable to assume that the American people were producing and using or exporting two and one-half times as much in manufactured commodities in 1919 as they did five years before. Everyone knows that the value of a dollar as measured by commodity in the later year was much less than in the earlier and that corresponding change in the so-called "value" of the manufactured products appears in these summaries. It is perhaps fair to assume that the index number for 1919 was 215 on a basis of 100 for 1914. In any event authorities on this subject disagree sufficiently so that this is as good an estimate as one can be sure of. If we divide 250 per cent by 215 per cent we get a result which is really representative of the ratio of commodity in the latter year to commodity in the former. By such division one can arrive at the conclusion that about 115 per cent as much of manufactured goods was produced in the country in 1919 as in 1914.

During the same period of five years we may assume that the population changed by about half as much as during the time between the census years 1910 and 1920, or in other words there was perhaps a 6 or 7 per cent increase in population. This change in population should be compared with the change in manufactured goods.

The standard of living of a country may be measured by the quantity of manufactured goods used per capita. This is by no means the only unit, but it is certainly one of significance. For such measurement it is necessary only to compare the 115 per cent in goods with 107 per cent in population. Thus we can safely conclude that there was by and large through the country an increase in the American standard of living. To say that it amounted to 6, 7 or 8 per cent according to just how one figures would be improper, for standards of this sort cannot be measured exactly in percentage.

Readers' Views and Comments

Chemical Patent Claims

To the Editor of Chemical & Metallurgical Engineering

SIR:—With reference to my article published in CHEMICAL & METALLURGICAL ENGINEERING May 18, 1921, pages 883-4, relating to the case of Miami Copper Co. vs. Minerals Separation Co., it has come to my attention that some readers have construed this paragraph as referring to the Callow cell. It was not intended to convey any such impression; the court found infringement in three previous steps of the process, including the Pachuca tank in which agitation was caused by the air-lift effect.

CHESTER H. BIESTERFELD.

Rhodium From Rodents

To the Editor of Chemical & Metallurgical Engineering

SIR:—Here is the claimant for your "Flor de Convolvulus Scoparius."

Do you know you gave me a very bad five minutes, being the interval between the time that I read your comment on my "rhodium" article and that required to get at the "Encyl. Britt." It was not that I was not well acquainted with oil of rhodium as a rat bait, but that a horrible suspicion seized me that I had spelled it wrong and that the plant might be rodium without the "h."

Your apology is most handsome so we will shake hands (across the sea) and part good friends.

Princetown, England.

THOMAS C. BRIDGES.

Exhibition for the American Ceramic Society

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to the editorial in your May 25 issue, in which you suggest an exhibition for the American Ceramic Society, you might be interested to know that the Art Division is working on a program which will assure the periodical exhibition of ceramic wares under conditions most favorable to each class of product.

Many members of the American Ceramic Society are also members of other organizations such as the Architectural League, National Academy, the National Woman's Painters and Sculptors, etc., and ideas dealing with the development and exhibition of artistic wares are being given serious consideration by these bodies.

An exhibition embodying anything like a representative collection of present-day domestic ceramic wares will be a rather large undertaking, and it is not expected that the first exhibition will do more than demonstrate the possibilities of a comprehensive show to every interest and activity in the ceramic field.

Without taking into consideration the many types of utilitarian and ornamental wares produced in this country, all of which should be shown in their respective groups, we have three classes of productive work, each one a powerful influence and force especially when their activities are co-ordinated, which is unfortunately not the case at this time, although serious efforts are being made to bring these forces together.

These three classes are: Factory production, studio production and school production. As the American Ceramic Society exhibitions are intended to be primarily educational in character, every effort will be made to show typical examples of all three classes.

While, as stated, these three active interests are working independently, often unsympathetically, and rarely possessing an appreciation and understanding of the importance and value of the others, there is happily a greater general interest in the development of artistic pottery and architectural faience than is often admitted by those who are too close to their respective activities to possess a true perspective. The Apprentice Schools of Design, the Art Alliance of America and many other organizations are actively interested. The press is giving due recognition to the need for development in ceramic art work. Your own valuable publication has been most liberal in this respect.

All of this goes to show that rational co-operative action among the interests mentioned is all that is needed to bring results, and this is the end toward which the Art Division is working.

Zanesville, Ohio.

FREDERICK H. RHEAD,
Chairman Art Division.

Treatment of Acid and Alkali Burns

To the Editor of Chemical & Metallurgical Engineering

SIR:—In regard to question of acid and alkali burns, published in your April 27, 1921, issue, may I state that in the Steffens department of beet sugar mills a rather painful burn is often experienced due to calcium saccharate? It has been my experience and observation that this unstable substance does not attack healthy, unbroken skin at all; but let there be the least contusion, scratch or friction from coat cuff or shoe, and there is trouble. The first stage is a redness with itching, which unless stopped passes to a peeling of the skin at various minute points. In these two stages a not too dilute acid will stop all further action. The third stage, which generally takes thirty minutes or longer to appear, is a number of small discolored, painless spots which are a true burn with tissue destruction. Unless drastic treatment is used here these burns will spread, grow and may run together to a very painful, sickly gray, sunken sore by the next day. I have seen them grow over night from almost unnoticeable points to the size of quarters.

In sugar mills accident cases are cared for in the laboratory. In one such laboratory the custom is to pour on rather concentrated acetic acid and make the workman walk across the laboratory before being allowed to wash off the acid. He is then stuck up with surgeon's tape and the result is generally successful. I prefer the more drastic, more painful, but absolutely certain treatment of using commercial HCl direct from carboy and leaving it on the burn till all effervescence (from the CaO) ceases, then washing well with water and soda and wiping with oiled rags. Burns then heal up in short order.

When one gets the saccharate in the eye it should be washed copiously with water—if none is handy, use

spittle—treat with weak acetic acid at once, and put in a few drops of olive or other equivalent oil. This stuff often slakes with mild explosion when in presence of hot water.

I am told that the barium saccharate is even nastier to handle from standpoint of burns.

Fort Morgan, Col.

M. SHERRILL.

Device for Measuring the Flow of Gases

To the Editor of Chemical & Metallurgical Engineering

SIR:—I noted with interest the comments by Messrs. Knowland, Donaldson and McCollum in your June 1 issue in reference to my paper "A Device for Measuring the Flow of Gases," appearing in your May 4 issue. It is possibly true, as pointed out, that my paper was misleading because it did not mention the corrections which should be applied in using the instrument calibrated with air. The object of my paper was merely to suggest the use of pipe fittings for building a measuring device. I pointed out that the principle was well known and therefore did not discuss it in detail. I am accustomed to make the corrections suggested, which are, of course, obvious, and I am sorry if anyone has been led to believe that the apparatus could be used without correcting the air calibration curve. The molecular weights of the gases that I have used are known and the corrections easily applied; with some gases it might be more difficult.

CARLE R. HAYWARD.

Mass. Inst. of Technology,
Cambridge, Mass.

The Tariff on Minerals

To the Editor of Chemical & Metallurgical Engineering

SIR:—In the article "The Tariff on Minerals," by Marc Pawl, in the June 8 number of CHEMICAL & METALLURGICAL ENGINEERING is included a paragraph on potash. It is unfortunate that the author did not take the trouble to get the facts before committing himself in writing. But facts do not always fit satisfactorily into a preconceived argument.

For example: Mr. Pawl makes the statement, "There is no likelihood of our being able to supply our needs from these sources" (natural brines). On the contrary, nothing is more likely. If the future of the industry is secured by adequate tariff protection, it would be easily possible for us to supply our needs from Searles Lake or Salduro Marsh alone inside of, say, two years. The potash is there and the methods of recovery are known. All that is needed is the capital to finance the plants, and this will quickly be forthcoming as soon as the future of the industry is reasonably secure. Searles Lake would keep us going at the present rate of consumption for seventy-five or a hundred years, and doubtless before that time our chemists will be making potash out of soda or some other element. But if they haven't accomplished this yet, we can start in on Salduro Marsh and run along for another century.

It is unfortunately true, as Mr. Pawl says, that we are still dependent on the German and French deposits for a large part of our potash, but there is no more reason for it than there was for our dependence on Great Britain for our tin-plate thirty years ago. If we had lacked the sense to protect our tin-plate people for a time, we should still be importing tin-plate instead of underselling the British in their own markets.

Mr. Pawl makes the statement that the proposed

tariff will add 75 per cent to the cost of potash. He does not mention the base upon which he figures his 75 per cent. . . . By some arithmetical gymnastics it is possible to figure the increase all the way from 20 per cent to 66 $\frac{2}{3}$ per cent, but to get up to Mr. Pawl's 75 per cent one must abandon facts and imagine a price which never was.

Finally, Mr. Pawl calls attention pathetically to the fact that the farmer will pay the increase. He fails to show that the proposed tariff will lay the appalling burden on the cotton farmer of not to exceed 30c. per acre. It will increase the cost of tobacco growing by the terrifying sum of less than three-tenths of one cent per pound. It will inflict on the potato farmer the frightful load of two or three cents additional cost per bushel.

Laying aside sarcasm, it is perfectly true that the farmer has his troubles and always will have until weather is made to order, bugs and plant diseases sent the way of the dodo and the Tasmanian, and marketing made a dead certainty. One of the American farmer's chief troubles in recent years has been the fact that he was so largely dependent on European sources for his potash. A small tariff for a temporary period will relieve him of this burden and at the same time enable the country to develop a new and important source of wealth and prosperity. In these circumstances, Mr. Pawl should shunt his pathos into some other channel and make an effort to help the good work instead of hinder it.

U. S. POTASH PRODUCERS' ASSOCIATION.

BY FREDERICK W. BROWN, Secretary.

Washington, D. C.

To the Editor of Chemical & Metallurgical Engineering

SIR:—I feel that if Marc Pawl is as poorly informed concerning other minerals as he is regarding flake graphite he should not be allowed the space in your valuable journal for his propaganda.¹

Mr. Pawl probably does not know that American business men have invested approximately \$6,000,000 in the development of Alabama graphite deposits alone; that Alabama could supply all the crucible stock and other flake graphite products required in the United States for years; that the quality of Alabama graphite is so much superior to Madagascar that the Quenelda Graphite Corporation, Liveville, Ala., was able to sell No. 2 flake graphite (second grade flake) in the open market at the same price as the No. 1 Madagascar graphite sold at during October, 1920.

Furthermore, Mr. Pawl probably does not know that the Bureau of Mines, U. S. A., under the direction of Mr. Stull of Pittsburgh, has proved that Alabama graphite can be used to better advantage in the manufacture of crucibles than Ceylon lump graphite, provided the manufacturer uses scientific methods in selecting and mixing his fireclay.

While Mr. Pawl is trying to protect the foreign investments of Americans, let him not forget the investments of Americans in American industries, without which we would have lost the European war.

Imports and exports are so much discussed these days that few people realize that these are only a small fraction of the total business of the country.

New York City.

CHARLES A. BURDICK.

¹EDITOR'S NOTE.—We do not regard Mr. Pawl's paper as propaganda, but rather as an unusual and interesting viewpoint of our mineral industries.

GRAND CIRCUS PARK IN THE HEART OF THE BUSINESS DISTRICT OF DETROIT

The Detroit Meeting of the American Institute of Chemical Engineers

Relation of the Chemical Engineer to the Automotive Industries Is the Keynote of the Summer Meeting—Papers Stress Metallurgy, Automobile Tires, Paint and Fuel—Excursions to Ann Arbor and Salt Mines at St. Clair

THE American Institute of Chemical Engineers met in Detroit, June 20 to 25, for the thirtieth semi-annual meeting. An enterprising local committee under the leadership of Chairman C. T. Bragg provided a week of pleasant and profitable entertainment and extended to the Institute the gracious hospitality of their busy and beautiful city. The well-rounded program included such interesting diversions as boat rides, dinner dances, banquets and barbecues. In addition to the usual business sessions there were excursions to the University of Michigan at Ann Arbor, and to the great salt mines at St. Clair. Many of the famous automobile factories and important chemical plants in the vicinity of Detroit were also visited by the chemical engineers.

The entertainment of the wives and feminine guests of members of the Institute was in the hands of a special committee under the direction of Miss Sarah Burnham of Detroit. The ladies' program substituted afternoon teas and shopping tours for the business sessions and plant inspections, but fortunately the programs converged for the dances and similar festivities.

REPORT OF COMMITTEE ON EDUCATION

The New York members of the Institute and their friends arrived in Detroit Monday morning after a boat trip up the Hudson to Albany and across Lake Erie from Buffalo. Immediately following their arrival President David Wesson called to order the first business session. The Institute was officially welcomed to the city of Detroit in a brief talk by John C. McCabe, research engineer for the city and personal representative of the mayor. Reports of the Council, the secretary and treasurer were then read by the secretary, J. C. Olsen. Dr. A. D. Little, chairman of the committee on chemical engineering education, presented as a progress report of his committee the tabulated results of the survey of chemical engineering courses in the principal universities and colleges of the United States. These tables, which had been

printed in a previous issue¹ of CHEMICAL & METALLURGICAL ENGINEERING, were used as the basis of an interesting discussion.

Dr. Little called attention to the great diversity of subjects included in 278 different courses offered by the institutions and pointed out the evident need for a certain amount of standardization. Other features of the report were the difference in the weighting of the various courses and the tendencies toward specialized instruction by certain universities, such, for example, as the courses in sugar at Louisiana, pulp and paper at Maine, and coal and ceramics at Illinois.

An interesting tabulation made by the committee showed that in ten important institutions the time devoted to chemistry lectures varied from 240 to 1,288 hours, with an average of 650 hours. The laboratory work ranged between 482 and 2,144 hours and the average was 1,148. Similar differences in requirements were shown to exist for the courses in physics, mathematics, mechanics and engineering. Additional charts and summaries are to be printed in the final report of the committee and the hope was expressed by Dr. Little that his committee might have the continued co-operation of the Institute in its study of this important subject.

FAVORS WORKING CLAUSE IN PATENT LAW

A report from the chairman of the committee on patents was read by the secretary and led to a discussion of the recent proposals to incorporate a working clause in the patent law. Henry Howard, who spoke in favor of such legislation, declared that the dye industry in this country had been throttled by the absence of a requirement for compulsory working of patents. Following other discussion, both favoring and opposing the working clause, a committee was appointed, with Mr. Howard as chairman, and was instructed to draft resolutions to Congress. These resolutions, presented and passed in a later meeting

¹CHEM. & MET. ENG., vol. 24, pp. 1047-53, June 15, 1921.

of the Institute, recommended the passage of a law similar to the British compulsory working act of 1907.

CHEMICAL ENGINEERING IN PAINT INDUSTRY

Dr. C. D. Holley, director of research for the Acme White Lead & Color Works, presented the first technical paper, which was an interesting account of "the manufacture and application of automobile finishes." Notwithstanding the fact that less chemical engineering has been devoted to the paint and varnish industry than to any of the other modern industries of similar magnitude, there are nevertheless certain engineering features worthy of mention. In many instances these developments from an engineering standpoint are directly attributable to the influence of the automobile industry, especially as related to quantity production.

FUME COLLECTION

One problem in the manufacture of varnishes which the chemical engineer has helped to solve has been the efficient collection and recovery of fumes.

"From 10 to 25 per cent of the weight of the varnish gums used is driven off in the melting of the gums. These products of decomposition pass up the varnish stacks and are disseminated in the air in quantities that sometimes reach several thousand pounds daily.

"This has necessitated the installation of an efficient fume control system whereby these fumes can be condensed as they leave the kettles or can be made to enter into a chemical combination and thereby be eliminated. This has required some really ingenious chemical engineering practice, as the problem was not an easy one to solve because of the physical and chemical nature of the fumes and the fact that the gums are 'run' in the varnish kettles at nearly their flash point and any undue disturbance in the equilibrium of the gases in the kettle often means a bad fire. These installations have proved quite successful, affording usable byproducts and in several instances have permitted a 50 per cent reduction in insurance premiums in addition to allowing the varnish maker to continue manufacture undisturbed by the authorities."

PYROXYLIN ARTIFICIAL LEATHER

Dr. G. C. Given described the manufacture of pyroxylin artificial leather. He pointed out that the enormous requirements of the automobile and furniture industries have greatly stimulated the manufacture of leather substitutes. The production of adequate quantities of satisfactory upholstery material has resulted in an industry in which there are now fourteen factories with a total invested capital in excess of \$50,000,000.

Of the three general types of leather substitutes—viz., vulcanized oils, rubber and pyroxylin—the last named is probably used in the largest quantity. In the manufacture of artificial leather from pyroxylin, the fabric is dyed and properly dried, and is then coated with a "dope" composed of special nitrocellulose, oil, solvent and pigment. This is spread on the cloth in successive thin coats numbering from five to fifteen, according to the quality desired. After the fabric has received the requisite quantity of coating, the product is passed into embossing machines which impress on the pyroxylin compound a grain resembling that of high-grade leather. For the production of the best qualities of artificial leather the embossed goods are

SCENE ON THE RIVER AT BELLE ISLE

finished by hand in order to obtain the artistic effects of old Spanish leather.

MONEL METAL

William M. Corse presented a paper on the properties and uses of Monel metal. This comparatively new and valuable alloy was originated in 1905 and was named after the late president of the International Nickel Co., Ambrose Monell. It is obtained from a nickel-copper ore of the Sudbury district, Ontario, and the metals in the finished alloy are in approximately the same proportion to one another as when found in nature. A typical analysis of the matte shows 67 per cent of nickel, 25 per cent of copper and 5 per cent of other metals, principally iron, manganese and silicon.

Mr. Corse indicated the principal uses of Monel metal in the automobile industry. Its silvery-white color, resistance to wear and the ease with which it is polished have made it a valuable material for door and brake handles, and for various dash trimmings. It has also been used satisfactorily in exhaust valves, spark-plug electrodes, and in float and needle valves for carburetors.

ANN ARBOR EXCURSION

One of the outstanding features of the Detroit meeting was the day spent at Ann Arbor as the guests of the University of Michigan. The trip was made from Detroit in special electric cars which arrived at Ann Arbor about the middle of the forenoon. The remainder of the morning was occupied in the inspection of the laboratories and buildings of the university. A pleasant half hour was spent in Hill auditorium, where Prof. Earl R. Moore gave an excellent organ recital. Luncheon was served in the Michigan Union building, which is a magnificent clubhouse erected on the campus by student and alumni organizations. President M. L. Burton of the university, in a short talk after the luncheon, emphasized the value of the present dual system of education and declared that the tax-supported universities of the West should receive the same recognition accorded the privately-endowed institutions of the East.

SOME CHEMICAL ENGINEERING IDEALS

Dr. David Wesson, in his presidential address, stressed the important work with which the Institute is connected and indicated the possibilities for future accomplishments. Dr. Wesson chose for his subject "Some Chemical Engineering Ideals" and said, in part, as follows:

"Painted on the wall of the library of the National

HILL AUDITORIUM AT ANN ARBOR

Engineering Societies' Building in New York is the following definition:

Engineering — the art of organizing and directing men and controlling the forces and materials of nature for the benefit of the human race.

"This definition is a very broad one and seems particularly adapted to defining the activities of the chemical engineers. It is a definition which arouses pride in our profession, for it indicates that the object of our profession is service—service for the benefit of our fellow beings.

"A glance through the list of members of our Institute will show that they are engaged in producing thousands of products which go to improve living conditions and at the same time provide means of earning a livelihood for multitudes. As an example, take the cottonseed oil industry alone. I mention it because it is the one with which I am most familiar. It gives employment in this country to 20,000 factory hands and 5,000 officers and salaried men, and all based on chemical engineering in developing the oil of a once despised waste product into valuable human food.

"Similar results are happening daily in other industries where the chemical engineer has had the opportunity to apply his knowledge. We see them in the field of metallurgy, fuel, mineral oils, tar, coloring matters and dyes, fiber products and paper, alkali acids and salts, glass and ceramics, building materials, paints, varnishes, india rubber, leather, glue, fertilizers, sugars and starches, foods and all sorts of organic products, photographic materials and explosives.

"The choice of the automobile as the keynote for the papers at this meeting is a particularly happy one. It is hard to conceive of any human production which embodies so many materials in its make-up as does this distance-destroying instrument of transportation. The papers read at this meeting will point out fully the part which the chemical engineer plays in making possible this modern means of travel.

"The automobile might well be taken as a symbol of the Institute. The industry started in a small way, and in twenty years has grown to world-wide importance. In the same way our Institute, starting modestly thirteen years ago, is rapidly growing into a national factor of economic and industrial importance.

"The first automobiles were built for pleasure

vehicles, and the industry was built up chiefly along the line of replacing the horse-drawn carriage. Now we see motor trucks displacing the dray and delivery wagon and competing with the railroad in the moving of merchandise. In the same way the Institute started out largely on an excursion, if not a joy-ride basis, but the responsibilities of the world war and the difficult reconstruction period which we are passing through have brought home to us all the idea that the Institute fulfills its highest ideals when it is rendering service to the profession and taking its part in national activities."

CHEMISTRY OF ROAD BUILDING

The relation of the chemical engineer to highway engineering was the subject of an instructive lecture by Prof. A. H. Blanchard of the University of Michigan. He declared that the status of the chemistry of highway materials is in a chaotic condition notwithstanding the fact that some work has been accomplished by federal, state and municipal laboratories. There is a promising field for the chemical engineer who can co-operate with the highway engineer in studying the physical and chemical properties of highway materials. The application of tar on asphaltum is an example of the faulty use of materials due to lack of knowledge of the properties of the two constituents. On the other hand, certain combinations of these materials have been successfully applied, but the need here is for the chemical engineer to supply the explanation. Before these combinations can be bought on specifications the chemist must devise more satisfactory tests and methods of analysis.

PROBLEMS IN NON-FERROUS METALLURGY

J. H. Ransom of the Michigan Smelting & Refining Co. read a paper entitled "Some Problems in Non-Ferrous Metallurgy." He laid emphasis on the fact that commercial metals are by no means 100 per cent pure, and the so-called "impurities," which as a matter of fact are mostly normal constituents, are likely to affect the resulting properties profoundly. In some cases alloying and remelting add to the total beyond that limited by safety, with the result that the metal becomes worthless. A probable case in point is the intercrystalline brittleness of lead, due to impurities segregated between the metallic crystalline grains. A

MICHIGAN UNION BUILDING

recently studied alloy of copper with about 15 per cent of nickel is also prone to this defect.

Minute amounts of unusual constituents often have a wholly disproportionate influence on the color, luster or "set" of an ingot, with a corresponding effect on its market value; inherently the metal may be undamaged. This effect had been studied carefully by the speaker, who concludes that changes in surface colors and other physical properties caused by a single additional element are usually characteristic and easily recognized. A combination of two or more impurities often causes greater perturbations than the same quantity of a single one, but in a few cases it was found that one addition counteracted a previous one. In general non-metals are more harmful than metals.

THE MOTOR FUEL PROBLEM

Prof. E. H. Leslie had prepared an exhaustive treatise on "The Motor Fuel Situation," but because of limited time, the paper was read only by title. Some of its salient features are reproduced here, however, as being of general interest.

"The motor fuel problem is one of the great problems of the present day. The solution demands readjustment and development in the petroleum and related industries, and in the automotive industries. Many of the problems are distinctly within the province of the chemical engineer.

"The consumption of gasoline is now nearly five billion gallons annually, and may be expected to increase to seven billion gallons. The United States produces two-thirds of the world's crude oil, but uses four-fifths of it. Our reserve supply below ground is 5,800,000,000 bbl., which, at a rate of production equal to that of 1920, would last only thirteen years. We are now dependent upon foreign crude oils, and are importing more crude oil than our combined exports of petroleum and its products.

"We cannot expect a further rapid expansion of the natural gas gasoline industry, nor can the distillation range of gasoline be further materially increased. Chemical research must point the way toward success in utilization of the heavier distillates as motor fuels.

"The most important single technical problem is the cracking of the heavier 40 to 50 per cent of petroleum, known as fuel oil or residuum. Processes now in use handle only the middle distillates.

"The use of aromatic distillates as fuel will never be of great consequence. Development of an alcohol industry based on wood as a raw material, and of a shale-oil industry, may be expected. Both are tremendous undertakings, and should not be expected to develop rapidly.

CRITICAL STUDY OF BOILING POINTS

Prof. E. M. Baker reported the results of some of the work growing out of the investigations of evaporator design which are being conducted in the laboratories of the University of Michigan. These investigations have emphasized the importance of a knowledge of the boiling points of solutions under reduced pressures. Mr. Baker and his associates have developed an apparatus capable of maintaining a reduced pressure constant at within 0.1 to 0.2 mm., and with this apparatus it has been possible to increase the accuracy of the boiling-point determinations to a greater degree than is required for any technical purpose.

They have made a critical study of boiling-point data and have found a general law which apparently holds rigidly for both concentrated and dilute solutions of all types, provided these solutions are not saturated and provided the dissolved substance does not itself exert an appreciable vapor pressure. This law is expressed by

the equation $K = \frac{t_1 - t_2}{\theta_1 - \theta_2}$ where t_1 is the temperature

at which a certain solution would boil at some pressure p_1 , and θ_1 is the temperature at which water would boil at this same pressure. Likewise, t_2 and θ_2 are respectively the temperatures at which the same solution and water would boil at a different pressure, p_2 . K is a constant for any given solution. Graphically, if the temperature of the solution is plotted as ordinates and the temperature at which water boils under the same pressure is plotted as abscissæ, the points for each solution will be on a straight line. This line represents the data for each solution more closely than any other smooth curve that can be drawn.

To illustrate how the law may be of assistance to the engineer concerned with evaporation and similar problems, we may assume that the temperatures at which a given solution will boil at two different pressures are known. Then the rule can be used to interpolate or extrapolate these data to other pressures, and the results will be as accurate as the original determinations. Thus the labor of investigating the boiling points of solutions under various pressures will be materially shortened.

The second paper, by Prof. Baker and V. H. Waite, presented the results of a critical study of the values given in the literature for the boiling points of calcium chloride solutions, supplemented by determinations using the law discussed in the previous paper.

SYNTHETIC AMMONIA PLANTS

The German and American synthetic ammonia plants were compared in an able manner by R. S. Tour, chemical engineer for the Nitrate Division of the Ordnance Department. The speaker was a member of the U. S. Fixed Nitrogen Commission, which inspected the German installations during the summer of 1919, and his paper showed the results of a very thorough investigation. The German plants studied were those at Oppau and Merseburg. Both were designed and built by the Badische Anilin und Soda Fabrik; the Oppau plant had a rated annual capacity of 100,000 metric tons of ammonia and the capacity of the Merseburg plant was 200,000 tons per year. The American plant at Sheffield, Ala., was rated at 10,000 short tons of ammonia.

The methods of operation and the types of equipment were compared by Mr. Tour, who also explained the details of the manufacture of the hydrogen and nitrogen required for the synthesis. The many interesting engineering applications need not be described here, since the complete paper will be published in a later issue of this magazine.

COSTS OF PRODUCTION

The consideration of costs has an important bearing on the synthetic process. The investment in the Oppau plant figured on the actual pre-war cost was estimated at \$270 per annual short ton of ammonia capacity or, roughly, \$100,000 per daily ton. The Merseburg plant, started during 1916, cost at least 50

per cent more, and by 1918 the costs of its construction had increased 150 per cent over the 1914 figure. (Investment per annual short ton of ammonia: 1914, \$270; 1916, \$400; 1918, \$700.)

The total cost of producing ammonia at the Oppau plant in 1914 was estimated to be 5.364 cents per pound. This figure was made up of the following items:

	Per Short Ton
Labor and operating	\$10.27
Fuel	18.00
Plant upkeep	43.66
General works expense	10.80
Fixed charges (interest, insurance, etc.)	24.55
Total cost per ton.....	\$107.28
Total cost per pound, \$0.05364	

VIEWPOINTS ON THE NITROGEN SITUATION

In summarizing the nitrogen situation Mr. Tour said:

"The true aspects of the problem are beclouded by the difference in viewpoint of those following or aiding its development. The research chemist realizes that the chemical problems are of the simplest nature except for the final step of the catalysis of hydrogen and nitrogen to synthesize ammonia. The designing engineer, on the other hand, feels that the development of a catalyst is a specific laboratory problem with which the research chemist is properly equipped to cope, but that the design of dependable equipment to operate at high pressures with temperatures at times approaching a red heat and with gases or liquids sometimes corrosive on the materials of construction is the really serious obstacle to success. The industrial interests have still another viewpoint; while appreciating only to a small extent the problems of the research chemist, the designing engineer and the operating chemical engineer, they rightfully feel that the success of these men is for them a failure if the resulting investment, fixed charges and operating expenses make the cost of the product prohibitive.

"The successful development of the synthetic ammonia process can be attained only by a full appreciation of all of these viewpoints."

RESOLUTION ON ALCOHOL

The last business session of the convention was held on Thursday, June 23. Prof. A. H. White pointed out the imminent danger to the alcohol industry contained in certain proposed legislation and he introduced a resolution to Congress calling attention to the legitimate needs of the chemical industries and favoring proper legislation for industrial alcohol. This was passed unanimously.

STUDENT MEMBERSHIP APPROVED

The Council of the Institute, after a consideration of the question of student membership, reported the following resolution:

Resolved, That the following amendment to the constitution be approved by the Council and recommended for adoption:

(1) That the Institute admit to its membership recognized chapters formed by students in chemical engineering at accepted institutions provided that at least one member of the faculty of the institution shall be an active member of the Institute and provided he shall act in an advisory capacity to such chapter.

(2) The constitution of each such student branch shall be approved by the Council.

(3) The members of such chapters shall receive the publications of the Institute and pay therefor such sum as the Council may determine.

(4) Members of the student chapters shall have the privilege of attending all meetings of the Institute.

Following a brief discussion by Professors White and Smith, the resolution was approved and referred to a committee for final drafting.

NICKEL-CHROMIUM ALLOYS AND HEAT-TREATING

W. A. Gatward discussed the application of nickel-chromium alloys to the heat-treatment of steel. He described the four general methods of heat-treating—viz., (1) annealing of steel parts, (2) malleableizing of cast iron, (3) heating for hardening and (4) carbonization or case-hardening. The application of nickel-chromium alloys in heat-treating furnaces was formerly carried on only on an experimental scale or for the production of small and expensive tools and parts. During the war a number of large installations were made by munition manufacturers and since then there has been a promising development in this field. It was claimed that electrical heating can compete with the fuel-fired furnace on a purely cost basis, but the strongest arguments in its favor are the improved working conditions and the higher grade product resulting from more carefully controlled temperatures.

AERONAUTIC DEVELOPMENTS

An informal talk on aeronautics was given by W. B. Stout. He discussed the recent developments in the aircraft industry, particularly the new all-metal type of plane which has largely been developed since the armistice.

The principal disadvantages of the wooden plane are the great waste in the selection of the spruce, the difficulty with which the wood can be tested, and finally the tendency of the plane to deteriorate due to the "letting up" of the glue and other causes. The metal plane, on the other hand, is constructed of material of very definite properties which can therefore be used with accuracy and precision.

OTHER PAPERS

Then followed two of the most interesting papers of the meeting. O. C. Berry of the Wheeler-Schebler Carburetor Co. spoke on the subject of "More Miles Per Gallon," and W. G. Nelson of Morgan & Wright discussed the determining factors in the life of a pneumatic tire. Both articles are to be published in early issues of this magazine.

Prof. James R. Withrow exhibited a new spray nozzle which was claimed to be very satisfactory for acid work. It was made of a high-silicon iron and is capable of giving a fine spray over a long period of operation.

A paper by Ludwig A. Thiele on the "Evolution of the Glue Industry and Grease Extraction" was read by title.

CONVENTION BANQUET

The closing event of the Institute's meeting in Detroit was the banquet at the Hotel Statler on Thursday evening. Following the bounteous repast and delightful musical entertainment, Toastmaster Alfred H. White called on Dr. O'sen, who spoke of some of the recent revelations of science. Responses were also given by Henry M. Leland, the father of the automobile industry, and Chester M. Culver of the Detroit Employers' Association. And finally the benediction was pronounced by President David Wesson in his pleasing and characteristic way and the convention adjourned until its winter meeting in Baltimore next December.

The Chemical Schedule of the Fordney Permanent Tariff Bill

An Analysis of the Proposed Provisions Affecting the Chemical Industries —Home Valuation of Imports and Restrictive Control of Dyes— Comparison of Rates in Previous Tariff Acts

THE Fordney bill for the revision of the permanent tariff, which was reported to the House of Representatives on June 29, represents the basis of what is perhaps the most important legislation to be passed by the present Congress. Its far-reaching effect on the future of industry and trade entitles it to the most serious consideration of all who are interested in our economic developments. The measure, framed along the well-known protective-tariff lines of the party in power, is the result of more than six months' work on the part of the Ways and Means Committee. It contains a great many unusual and untried provisions which make it difficult to compare it with previous tariff legislation or to render an accurate judgment on its probable operation.

The new tariff bill must be regarded as still in an experimental and tentative stage, for before its final enactment it will be the subject of many hours of heated debate and discussion, of political maneuvering and compromise. Some amendments will be accepted from the floor of the House, a more or less complete revision will probably be made by the Senate Finance Committee, and when, perhaps six months from now, it is signed by the President and finally becomes a law, it may bear but slight resemblance to its present form.

HOME VALUATION OF IMPORTS

One of the outstanding features of the proposed measure is the adoption of the domestic valuation of imports as the basis of assessing ad valorem duties. The change from the long-established use of the foreign market value has been made principally because of the instability of foreign exchange and the widely varying costs of production here and abroad. Section 402, which expresses "the legislative intention that duties ad valorem shall be assessed upon the fair market value of the merchandise *in the United States*" defines the dutiable value as:

* * * the price on the date of exportation of the imported merchandise at which comparable and competitive products of the United States were ordinarily sold or freely offered for sale in the usual wholesale quantities and in the customary wrappings, coverings, and containers, whether holding liquids or solids, to all purchasers in the ordinary course of trade, including all costs, charges, and expenses, in the principal market or markets of the United States; . . .

In cases where this value cannot be ascertained to the satisfaction of the appraising officer, certain alternatives are provided, based either on the foreign value of the imported goods with certain additional charges or on the costs of production plus shipping and selling expenses, duties and commissions.

The change to home valuation will have the obvious effect of increasing the amount of revenue to be obtained from a given ad valorem rate of duty, so for that reason a substantial increase in protection has been effected by an apparently slight advance in the ad valorem rates.

The Fordney bill presents many other innovations in

tariff legislation; a new scheme has been adopted for numbering the various schedules and the paragraphs within the schedules. There have been many changes in classification and phraseology and the administrative sections contain a number of new provisions giving the President the power, under circumstances warranted by the trade of the United States, to impose retaliatory duties or to adjust the rates along the principles of a bargaining tariff.

RATES IN THE CHEMICAL SCHEDULE

A critical examination of Schedule 1—Chemicals, Oils, and Paints—reveals comparatively few ad valorem duties higher than the general level of 25 per cent. The principal exceptions are in the cases of products of industries which have developed since the outbreak of the war, such for example as coal-tar dyes and medicinals, hydrosulphites and sulphonylates, synthetic organic chemicals, perfumery and toilet articles, and the products derived from acetylene and other hydrocarbon gases. The general rate of 25 per cent ad valorem is carried by the all-inclusive paragraph 5, under the general provisions of which have been included hundreds, if not thousands, of "chemical and medicinal compounds, preparations, mixtures and salts, not specially provided for." This rate is at least double the basic duty of 15 per cent on the foreign market value provided by the present law, and is a slight increase over the general level of the Payne-Aldrich tariff of 1909. Because of the change in the basis of valuation it is difficult to compare the rates between this and the earlier protective tariff, but of 100 duties in Schedule 1, 47 were found to be the same as in the Payne law, 27 are higher and 26 are lower. The rates in the Fordney bill on the principal chemicals are compared with those in the two preceding tariff laws in the accompanying table.

CONTROL OF DYE IMPORTS

By far the most significant feature of the chemical schedule is the special protection accorded to dyes and intermediates, pharmaceuticals and other products derived from coal tar. Not only are higher duties imposed, but for a period of three years these products cannot be imported unless the importer complies with certain very specific conditions. Dyes and other coal-tar chemicals which are manufactured in the United States and are obtainable on reasonable terms as to quality, price and delivery cannot be imported under any conditions. Products not being made here or for which the domestic supply fails to meet the requirements of satisfactory quality, price or delivery can be brought into the United States only by an importer registered with the United States Tariff Commission, and the total importation must not exceed a six months' supply for the actual consumer of the dyestuff.

This restrictive control of imports follows along lines somewhat similar to the "selective embargo" proposed

in the Senate during the last session as a substitute for the licensing scheme of the original Longworth bill. The section giving the Tariff Commission the power to determine reasonable terms as to quality, price and delivery is practically identical with the corresponding sections of the earlier bill. The new provisions, however, definitely establish the procedure by which the United States Tariff Commission is to administer the control. All of the articles in the paragraphs covering intermediates and finished coal-tar products are to be divided into two classes. Class A, which includes the non-importable products, is published in the form of a list, and this list may be revised, from time to time, at the discretion of the commission as the result of its investigations or following hearing of complaints. The commission is also required to publish a list of persons who have registered with the commission and are therefore permitted to import dyes under the above regulations.

The limitation in regard to the quantity of imports is accomplished by requiring the importer (or the actual consumer if the importer is acting as an agent) to furnish the collector of customs with an affidavit stating that "the quantity to be delivered will not place him in possession or control of more than a six months'

supply." Exception is made in the case of those goods which are sold in small packages through the retail trade, for which it would obviously be impossible to ascertain consumption during any limited period. Other sections of the dye schedule provide for the transfer to the Tariff Commission of the former War Trade Board Section, and also establish penalties for failure to comply with the regulations for administering the act.

Objections will probably be raised to this or any other form of restrictive control, on the familiar grounds of "less government in business," but the supporters of the bill point out the important relation of the dye industry to the national defense, and as a proof of their contention that a high tariff alone is inadequate, they cite the example set by England and France, which have already protected their dye industries by embargoes or similar measures. The coal-tar provisions include, in addition to dyes and intermediates, such materials as color lakes, pharmaceuticals, photographic chemicals, synthetic perfumes and flavoring materials, synthetic tanning materials, synthetic phenolic resins, explosives and all other products "when obtained, derived or manufactured in whole or in part" from coal tar.

FERTILIZER MATERIALS BECOME DUTIABLE

For the first time in tariff history imported fertilizer materials are to be taxed. A duty of three-fifths of a cent per pound is imposed on ammonium sulphate, presumably to encourage the development of byproduct coke ovens and to protect the domestic industry from possible competition of Germany's nitrogen fixation plants. These plants, built under the stress of military necessity, are reported to have the capacity to produce almost double the entire world's pre-war requirements of ammonium sulphate. The development of the by-products industry in our own country has reached the stage where it now supplies the domestic consumption, with a small exportable surplus, so it is not likely that the duty imposed will materially affect the ammonia trade. An additional factor of safety is the stabilizing influence of the competition with Chilean nitrate.

THE DUTY ON POTASH

The bill also provides a duty on crude potash salts, which will probably be felt somewhat more seriously, since, for the present at least, it will be necessary to import more than three-quarters of the country's requirements. The domestic producers, whose output in 1920 supplied only about one-fifth of our normal consumption, maintain that with the five years of protection afforded by this bill they can increase their production to the extent that the country will be practically independent of the German and Alsatian supplies. Whether or not this can be accomplished will depend to some extent upon the solution of the transportation problem, and possibly, in the case of the Searles Lake

producers, to the development of a water route through the Panama Canal. The duty on potash salts is to be on a declining scale. Starting with a maximum of 2½c. per lb. of actual potash for the first two years, the duty is reduced to 2c. for the third year, 1½c. for the fourth, 1c. for the fifth, and thereafter the imports are to be free of duty. For a period of five years a compensating duty of 15 per cent ad valorem is added to the regular rates on the refined potassium salts included in paragraph 75 of the chemical schedule.

OTHER INDUSTRIES RECEIVING PROTECTION

Other industries to be recognized by the new tariff are barytes and barium chemicals, magnesite, crude botanical drugs, synthetic camphor, and hydrogenated, vulcanized and other chemically treated oils. Chemical manufacturers will be interested in knowing that pyrites is to remain on the free list. The duty of \$4 per ton on crude barytes may be regarded as a compromise between the demands of the consumers along the Atlantic seaboard and those of the inland producers. With present freight rates the duty provided is not sufficient to permit the Missouri barytes to compete in the New York market, but it is questionable whether or not this could have been accomplished without giving undue advantage to the Georgian producers, who are more strategically located. Barium carbonate, chloride, dioxide and nitrate are given slightly higher rates than in previous tariffs in order to compensate for the duty on the raw material.

Another war mineral to become dutiable for the first time is magnesite, which is an essential material for

the manufacture of refractories and certain cements and stucco. Here too the fixing of the exact rate of duty involves the serious problem of transportation. The centers of production and consumption for this comparatively cheap material are separated by the width of the continent.

CRUDE BOTANICAL DRUGS AND SYNTHETIC CAMPHOR RECEIVE PREFERENTIAL TREATMENT

When the late war cut off the supply of certain indispensable botanical drugs their cultivation was attempted in the United States, and, in certain instances, with conspicuous success. The most important of these products, belladonna, digitalis, stramonium and henbane, have been given preferential treatment in the drug provisions of the new tariff.

Tariff laws in the past have generally imposed a duty on camphor for the purpose of raising revenue. A slight differential has sometimes been allowed between the crude and refined camphor and this has resulted in developing some refining in this country. The bulk of our large requirements, however, is purchased from the Japanese monopoly in the form of crude camphor. An ad valorem duty of 25 per cent on all forms of camphor is imposed presumably to encourage the manufacture of synthetic camphor, since the development of this new industry is apparently the only way that this country can become independent of the great foreign monopoly.

RECLASSIFICATION OF CHEMICALS

Most of the changes in the phraseology of the new tariff law are those suggested by the Tariff Commission in its report on reclassification. For example, the duties on acetic, lactic and tannic acids are based on standards of strength in order to avoid the unsatisfactory operation of the single specific duties imposed by the present law. By combining all of the dyeing and tanning materials of vegetable origin in a single provision, the customs officials are relieved of the difficulties of separate classifications based on use. A more logical and scientific classification of the oil provisions separates the animal oils, the expressed vegetable oils and the essential oils, and new paragraphs have been added for sulphonated oils and soluble greases, for hydrogenated, vulcanized, chlorinated and other chemically treated oils, and for the mixtures and combinations of animal, vegetable, and mineral oils. Radical changes have been made in the provisions dealing with perfume materials and perfumery. The principal raw materials such as the flower oils and floral products, and musk and other animal perfumes, have been transferred to the free list, although under the present law these articles are taxed for revenue purposes. The synthetic perfumes derived from coal tar are included in the provision for coal-tar products; those derived from the essential oils and non-coal-tar sources are given a protective duty of 35 per cent ad valorem. A more significant reclassification is found in the provision for mixtures and combinations of the various perfumery materials, which become dutiable at the comparatively high rate of 40c. per lb. and 40 per cent ad valorem. By imposing this higher duty the Congress evidently intended to develop the manufacture of perfumery from the primary raw materials and to prevent the practical evasion of the duties on finished perfumery by the importing of semi-finished and carefully compounded preparations.

The proposed duty of 35c. per bbl. on crude petroleum oil and 25c. on fuel oil is perhaps not to be regarded too seriously. Its transfer to the chemical schedule from the free list was accomplished at the last session of the committee and the corresponding correction had not been made in the printed copy of the reported bill. It is interesting to note, however, that gasoline, benzine, kerosene and other refined petroleum products remain on the free list, notwithstanding the duty on the raw material.

It has been possible here to comment upon only a few of the many features of the new tariff, but the importance of the measure merits the careful study of all who are interested in the development of our chemical industries.

Avoid Temperature Shocks in Heat-Treatment

The A.S.T.M. committee on heat-treatment of iron and steel submitted the following notes to the recent convention at Asbury Park, N. J., as covering helpful information:

The advantage of alloy steels over simple steels lies in the fact that they are more sensitive to heat-treatment and capable of giving higher properties when properly handled. The increased sensitiveness to treatment unfortunately is accompanied by a proportionate sensitiveness to failure during treatment, which requires greater care in all treatment operations and necessitates the elimination of abrupt changes in section. The following suggestions are made to overcome this difficulty:

1. Heavy solid alloy forgings should not be allowed to cool, but should immediately be put in an annealing furnace and normalized.

2. High nickel-chrome, chrome-vanadium or any other alloy steel bars and small forgings liable to shattering should be cooled slowly after rolling by burying in warm ashes or lime to retard the cooling. High carbon, even with a moderate alloy content, increases the risk of cracking.

3. A thorough annealing or normalizing above the upper critical point after rolling or forging eliminates much danger of later troubles due to cracks and strains and leaves the metal in a better condition to secure the maximum effect of the quench.

4. Annealing only does not develop high physical properties, but leaves the metal soft, uniform and ductile. To break up forging and rolling structures which are detrimental the piece should be double annealed, first at 100 to 200 deg. F. above the critical range followed by an anneal slightly above the critical range.

5. In heating for either annealing or quenching, the piece should be slowly and uniformly brought to temperature, the rate depending on grade and section, especially through the brittle range, which is up to 800 deg. F.

6. For quenching, the piece should be uniformly heated above the critical range and introduced into the quenching medium with no delay after leaving the furnace.

7. Quenching is the most drastic treatment operation, and therefore the most dangerous. Alloys or sections subject to water cracks should be quenched in circulating oil.

8. In drawing after quenching the piece must be slowly and uniformly heated to the proper temperature, but may be cooled slowly or rapidly as desired.

Albert Sauveur, Honorary Member of Steel Treaters

ALBERT SAUVEUR, professor of metallurgy at Harvard University, Officer of the French Academy, Elliott Cresson Medalist, was notified of his election to honorary membership in the American Society for Steel Treating on the occasion of his address before the Cleveland Section of that society on the "Dendritic Structure of Steel." In accepting the honor he honored the donors, who have thus added to their notables a leader in metallurgical thought and writing among technologists both here and abroad.

Coming to America fresh from the School of Mines at Liège, Belgium, Albert Sauveur matriculated in the Massachusetts Institute of Technology and received there the degree of Bachelor of Science in Mining and Metallurgy in 1889. Thereafter for eight years he served his novitiate as chemist and metallurgist—and in those days metallurgists were far more rare than chemists—for the Pennsylvania Steel Co. and the Illinois Steel Co.

W. R. Walker, manager of the South Works of the latter company, asked young Sauveur to take up the microscopical examination of iron and steel, which had received some attention both in England and in France. There was an old microscope available, and he was given an empty room in the laboratory. While waiting for table, desks and other equipment, a barrel served as a metallographic bench, and diffused sunlight replaced a better illuminator. From this hurried beginning he created that early work which was destined to have such a wide influence on the manufacture and heat-treatment of steel. The first application of microscopic evidence was to throw light upon apparently unexplainable variations in the quality of steel rails. A close examination of metallic structure seemed so pregnant with possibilities that the subject has since been followed keenly by him, his interest never flagging, and as a result it is no exaggeration to say that he has done as much as any other man, if not more than any other man, to bring metallurgy to its present important place as a method of routine testing and fundamental research.

That early work at Chicago extended into an investigation on crystallization in steel, and some of his results were read before the 1893 Chicago meeting of the American Institute of Mining Engineers. He had already set for himself the concrete problem, "What heat-treatment will best suit a given chemical composition so as to get a certain desirable structure, and

with it certain other desirable physical properties?"—a problem which is as important now as then, and even yet capable of solution only in special cases.

This first contribution to the literature showed that Sauveur had already diagnosed the relative effect of temperature, degree of work, rate of cooling and chemical composition on grain size of steel products. He had devised and used a method of measuring grain size without the necessity of photographing the specimen, and constructed curves showing its relation to the tensile properties and ductility of bessemer rails. His paper clearly shows, and in a way which then was unique in technical literature, that the finishing temperature and size of section has a great effect on the structural heterogeneity in a steel rail.

Such pioneer work on the industrial applications of metallography may be appraised only in the light of the amount of information regarding the science then available. To illustrate: At the same meeting, Osmond, the French savant, presented a paper on "Microscopic Metallography" covering such subjects as methods of illumination (now considered very elementary), and presenting micrographs of typical commercial steels, concluding briefly that "it is difficult to offer, even hypothetically, a satisfactory solution" of the reasons for difference in structures.

A worker of the Sauveur type could not long dodge the question, "What causes hardening?" and in 1896 he wrote another paper for the American Institute of Mining Engineers on "Microstructure of Steel and the Current Theories of Hardening," which summarizes to that date the ideas of various metallurgists on the reason for

the hardening of steel, and presents data of his own bearing upon the subject. This provoked such a discussion both in America and abroad that the paper marks an epoch in the history of heat-treatment. It was critically discussed by such men as Howe, Arnold, LeChatelier and Osmond, the latter presenting in a long contribution one of his first contributions to scientific information on the allotropy of iron, a new conception which has been widely accepted and has had such a strong influence on the theory and practice of heat-treatment of iron and steel.

At that time austenite had not been established as the solid solution of carbon in gamma iron—in fact martensite was thought to be the constituent stable at a high temperature, and on cooling it first precipitated excess ferrite (in low-carbon steels) and finally the residual portions transformed into pearlite. After marshaling the main evidences in favor of the various

ALBERT SAUVEUR

theories of hardening he writes in this article: "Martensite is the constituent which confers hardness upon suddenly cooled steel. If we knew its composition, the mist which now surrounds the phenomenon of hardening would be cleared away." With a truly remarkable clearness of judgment he presents his own conclusion from the evidence—namely, that martensite is carbon dissolved in iron—and proposes the idea that the hardness of martensite is essentially due to the distribution of carbide in the mass! This paper was written twenty-five years ago, and in his later writings Prof. Sauveur favors the view that hardness of martensite is due to beta iron with carbide in solution, yet does not the earlier conclusion remind one of the "critical dispersion" hypothesis of hardening lately supported by our friends the colloid chemists?

A KEEN AND WITTY EXPERT WITNESS

As the senior member of the firm of Sauveur & Boylston, such keen insight has in later years brought him great repute as an expert in important patent litigation. Sauveur always goes straight to the heart of a matter, and is always able and ready to clear up difficult points in the minds of attorneys and judges. This, without losing patience with legal obtuseness, without forgetting to temper the caution of the trained expert with common sense. After all a lawyer is only a human being, and wit often brings a laughing understanding with even a metallurgist.

In 1899 he was called to Harvard University as instructor and was assistant professor in metallurgy and metallography from 1900 to 1905. He lectured on metallography at the Massachusetts Institute of Technology until 1903. Since 1905 he had been professor of metallurgy at Harvard. He found time to edit the *Metallographist* (1898-1903) and its successor the *Iron and Steel Magazine* from 1903 to 1906. The latter magazine in turn was merged with CHEMICAL & METALLURGICAL ENGINEERING, then called *Electrochemical and Metallurgical Industry*.

Naturally his publications have been many. He is best known to metallurgical students for his wholly admirable "Metallography and Heat-Treatment of Iron and Steel," published in 1912 and since passing through several editions. Its information is contained in simple language, written in a clear style, arranged in a very orderly manner and illustrated not only with well-chosen micrographs but with a number of very original graphic diagrams.

As a teacher he is beloved by his students for his fairness, never failing courtesy and his clear explanation of difficult points, his quick sense of humor and ready wit driving home each principle or detail to the pupil. Dignified, yet alert to discern the fallacy in an argument of student or associate, he is nevertheless able to set either one right without offending. Prof. Sauveur is always patient with errors of students and employees, and gives his orders chiefly by means of suggestions which nevertheless convey his desires, leaving no doubt in the mind of the hearer as to the importance of the work in hand.

Despite the many duties of his post at Harvard, he has always been generous with time and thought for the good of our Government and the profession. In 1917-19 he was metallurgist of the American Aviation Commission in France and later director of research for the Metallurgical Division, Air Service, A.E.F., stationed in Paris, France.

Large Production of Fullers Earth in 1920

The production of fullers earth in 1920, according to a statement made public by the United States Geological Survey, was 128,487 short tons, valued at \$2,506,189, or \$19.51 per ton. These amounts represent the largest output, the largest value and the largest average price ever recorded. The output was 21 per cent greater than in 1919; it was more than three times as great as in 1913 and nearly nineteen times as great as in 1895, the first year of production. The value in 1920 was 25 per cent greater than that in 1919, nearly seven times as great as that in 1913, and sixty times as great as that in 1895. The average price per ton in 1920 increased only 4 per cent over that in 1919.

Fullers earth was produced in eight states in 1920; named in the order of their rank in output they were Florida, Georgia, Texas, Alabama, Nevada, Arkansas, California and Massachusetts. Promising deposits of fullers earth have been discovered also in Pennsylvania and Virginia. The Southern States reported 99 per cent of the output, Florida alone reporting about 85 per cent of the total.

The imports of fullers earth, which for many years constituted the entire source of supply, also increased in quantity and value in 1920. During the war these imports naturally decreased in quantity, and with the cessation of hostilities they just as naturally increased. The imports in 1918 were about 50 per cent of the maximum (24,977 short tons in 1914); in 1920 they were 77 per cent of the maximum. During the war some refiners of edible oils and fats—by whom the imported fullers earth is probably used exclusively—were unable to obtain a sufficient supply of foreign earth and were compelled to adapt domestic earth to their needs, and it may be that imports of this material will never again be so essential to the American industry.

The imports of fullers earth in 1920 were 19,235 short tons, valued at \$221,893, or \$11.54 a ton. These amounts represent an increase of 39 per cent in quantity and of 17 per cent in value.

The average price at the markets of the country from which the material was imported decreased \$2.13 a ton.

Production of Bauxite in 1920

According to figures collected by the United States Geological Survey, 521,308 long tons of bauxite, valued at \$3,247,345, was produced in the United States in 1920, as compared with 376,566 long tons, valued at \$2,201,747, in 1919.

The mines in Saline and Pulaski counties, Arkansas, produced 481,279 long tons, or 92 per cent of the total output in 1920. The production from these mines in 1919 was 333,490 long tons.

Georgia ranked second, Alabama third and Tennessee fourth in production, and the combined output of these three states was 40,029 long tons in 1920, as compared with 43,076 long tons in 1919. In Georgia the bauxite-producing counties, arranged in order of quantity produced, were Sumter, Wilkinson, Floyd, Randolph, Meriwether, Macon and Bartow. A number of the mines in Bartow and Wilkinson counties that were worked in former years have been abandoned, but new deposits in Randolph County were opened in 1920.

The bauxite imported in 1920, most of it from South America and France, amounted to 42,895 long tons, as compared with 6,082 long tons in 1919.

The Latent Heats of Fusion of Nickel and Monel Metal

Description of Apparatus and Manipulation for Precise Determinations of Specific Heat of Solid or Liquid Metals—Results Found Indicate That Formerly Published Figures Are in Error by 30 Per Cent

By WALTER P. WHITE

THE present paper deals with the two important metals nickel and copper. The work was done with considerable care; hence it is hoped that the results obtained will, besides being of value themselves, also prove useful as a check on other series of determinations in which these two metals are included.

Latent heat determinations of any sort above 1,000 deg. have not been numerous. The 1913 edition of Landolt and Börnstein contains latent heats of only four metals melting above 1,000 deg.—platinum, palladium, cast iron and copper—and none of these is really modern.

In 1918 Wüst, Meuthen and Durrer published¹ specific and latent heats, obtained by a very bold and interesting method, of numerous metals, including nickel, iron, cobalt, manganese, copper, gold and silver. This extensive research is thus our main source of knowledge of metallic latent heats above 1,000 deg.

The value for the latent heat of nickel obtained in the present work, 73 calories per gram, is very different from Wüst's value, 56 calories. There is evidently a large error somewhere; hence the probable error of the present work will be considered very carefully.

GENERAL METHOD

The method employed was the familiar one of heating the specimens of metal and then dropping them into a water calorimeter. Some special features of the particular arrangement used will be described at the end of this paper. The arrangements concerned in the temperature measurement in the furnace are of first importance, since this measurement presents the greatest uncertainties and therefore mainly determines the probable precision attained. The other errors, in weighing, in the dropping process and in the calorimeter, are negligible in view of the precision sought, which was from 3 to 10 per mille, and all that the purity of the metal samples warranted.

The metal specimens, about 27 g. in weight, were used in closed silica glass tubes, which protected them from oxidation and supported them while melted. To avoid bursting at the high temperatures the tubes were nearly exhausted before sealing. This necessitated first drawing out a thick-walled capillary. I am greatly indebted to Dr. E. G. Zies of this laboratory for this difficult work on the silica glass. The tubes sometimes collapsed, which did no harm. Before exhaustion they were filled with nitrogen, but the trace of gas left would have been negligible if it had been pure oxygen. If the nitrogen did any good, it was in protecting the metal during the inclosing process.

The furnace cavity was vertical, 2.8 cm. wide by 25 cm. high. Three platinum-faced partitions at each

end shut off, in part, the heat loss at the ends, and left an inner working chamber about 16 cm. high. In the center of this hung the silica glass tube containing the metal cylinder. The tubes were 13 mm. in diameter outside, and about 6 cm. high. In the 6 mm. annular space around the tube was the platinum-rhodium thermocouple which served as a thermometer. This couple agreed throughout, within 1 deg., with a carefully-kept standard, which had been calibrated against the original "Element G" of the Day-Sosman high-temperature scale determination, confirmed by gold, silver and palladium meltings. The only remaining uncertainty in the temperature of the metal specimen lies in the difference of metal and thermometer, and since the temperature measurement in the furnace is the only appreciable source of error, this difference mainly determines the precision attained. This difference was directly observed by combining with the regular couple a differential couple of fine wire (0.2 mm.) running to a heavy-walled platinum cylinder in an unsealed silica tube. This platinum cylinder took the place of the nickel or Monel cylinder, which could not well be used in a tube left open for the passage of the wire. The results of two series of observations on two successive days are shown in Table I. There is a

About 12 microvolts = 1

* The time when 1,256 deg. was reached on Nov. 12 was not noted, since its importance was realized only as a result of the experiment of this day. This time is therefore inferred by comparison with the curve for the next day, and is doubtless affected by a small, unimportant error.

¹F. Wüst, A. Meuthen and R. Durrer, "Thermal Constants of Technical Metals," *Ver. deutsch. Ing. Forschungsarbeiten*, No. 204, 1918.

change with time which is sometimes greater than the minimum value of the temperature difference. The direction of this change shows that it cannot be due to the lag of the tube or metal. It arises no doubt from a very protracted warming up of the ends of the furnace. After the first ten minutes an uncertainty of ten minutes in time evidently produces less than 2 deg. error.

Three degrees was the greatest change in the differential temperature reading produced by shifting the tube 4 mm. A greater change might conceivably occur in practice from a tilting of the tube in the furnace, but 10 mm. was the maximum possible displacement in this case, and 8 mm. is more than is probable. The greatest error from this source, then, is not likely to be over 6 deg. These errors in temperature are, for timing, 0.14 per cent of the specific heat, and for position, 0.4 per cent. The agreement of the results, to 0.6 per cent or better in all the metal drops but one, with errors

from every source included, confirms in an entirely independent way the estimates just made of the magnitude of the errors. It is clear that this applies to the systematic as well as the accidental error, since the only way for a systematic error to enter would be in case the temperature difference from thermojunction to metal were different during the initial test from its value at all other times. Any large variation of this sort is very improbable in view of the small magnitude of the observed discrepancies throughout the work.

EXPERIMENTAL RESULTS

In order to correct for the heat given out by the silica tube, trial tubes, loaded with the platinum cylinder, were dropped at two temperatures, 1,260 deg. and 1,400 deg. In this way the mean heat loss in the drop was also corrected for, and only the irregularity of this heat loss remained to affect the results, since this loss was not affected by having the metal inside the container. These tube determinations appear in Table II.

*An accident stopped the stirring, but late enough in the experiment so that the uncertainty was only a part of the leakage correction, or about 1 per cent. Since the est. estimate proved to coincide almost exactly with 19, a repetition would have added little to the probable accuracy of the result as now given.

The results of all complete determinations, with the magnitude of all the important quantities concerned, are given in Table III.

The latent heats are found as the difference of total heat of fused metal and total heat of solid metal at the same temperature. It is well known that impurities cause an incipient melting which may falsify the observed specific heat of substances over a temperature interval of many degrees below the melting point. For this reason the observations on solid metal were taken at temperatures nearly 100 deg. below the melting point or interval, and these values were used to calculate the total heat up to the assigned temperatures of melting. The values of specific heat assumed over the calculated interval were taken, somewhat arbitrarily, as the mean specific heat up to the temperature of observation and were, for nickel, 0.134; for Monel metal, 0.128. Since the specific heats of these metals do not vary rapidly in this region, the assumption cannot involve appreciable error. The difference between the specific heat of solid and liquid metal, also, is small enough so that a variation of 20 deg. or so in the assigned melting temperature makes little difference in the heat of fusion of nickel, and the assigning to Monel of a latent heat at a single temperature, instead of over an interval, leads to a value for this latent heat which has nearly the precision of the observations and is positively defined. It seems impossible to do any better until we have more reliable values for the various specific heats concerned.

RESULTS FROM POURING MOLTEN METAL

Before the work in silica inclosures was undertaken, the total heat of melted nickel was found by pouring the metal directly from crucibles into the calorimeter, using the first appearance of solidification to indicate the temperature, which was therefore the melting point. About 60 g. was taken, and the rate of cooling of the charge was necessarily very rapid, perhaps over 100 deg. a minute. Some practice was required in catching the right moment for pouring; the last two samples left some solid metal behind in the crucible. These results are also given in Table III. The method, at the stage to which we carried it, was still somewhat subjective, and the excellent agreement with the electric furnace determinations does not so much add to these as show something of the excellence of the pouring method. These pouring results do, however, furnish a very convincing and largely independent confirmation of the others in so far as they indicate that Wüst's result for the total heat of melted nickel is too low by an amount corresponding to a temperature difference of about 120 deg. For two things show that the poured nickel in the two cases can hardly have been 120 deg. high, and probably

not 20 deg.: the fact that solid metal was left behind, and the fact that the measured gas furnace temperature was only 50 deg. above the melting point when the crucible was removed, to be cooled some seconds in the air before pouring. In a third pouring there was doubt about the weight of the metal, hence this is not reported. Thanks are due to A. F. Buddington, then of this laboratory, who attended to the furnace and the pouring while the temperatures were being read electrically in the room above, and to C. M. Saeger, Jr., of the Bureau of Standards, who furnished a number of small zircite crucibles which stood excellently the rather severe treatment involved in the manipulation. This pouring method is evidently not so well adapted to an alloy like Monel, which has a melting interval.

Analyses of specimen metals after the determinations, kindly furnished by the International Nickel Co., are given in Table IV. They seem to show quite clearly that appreciable oxidation, either of metal or impurities, did not occur in any case, and hence that no appreciable heat from this source falsified the determinations. There was, moreover, no opportunity for oxidation during the drop of the inclosed specimens, since the silica tube was usually heard to crack, under water, about a minute after it was dropped. The metal cylinders, weighed after the experiment, showed no change as great as

TABLE IV. COMPOSITION OF THE METAL SPECIMENS

	Specimen		Specimen	
	Before	After	Before	After
Copper	0.16	0.17	28.0	26.39
Nickel	99.1	99.62	63.0	69.83

Carbon	0.10	0.10	0.18	0.15
Manganese		0.10	1.50	1.74

1 mg. for the unmelted specimens; after melting there were negligible changes of 10 mg. or less, and even these were probably due to reaction with the silica glass, of which there were clear indications.

WÜST'S METHODS

For comparison it seems desirable to review, briefly, Wüst's methods. His furnace was in a highly exhausted tube, which extended down into an ice calorimeter. The solid metals were ordinarily used bare, but were inclosed in silica glass when they were to be melted. Comparisons with the three solid metals silver, gold, copper up to 900 or 1,000 deg. showed no difference, due to inclosure, in the specific heat so observed. The furnace thermel—i.e., thermoelectric thermometer—which was, as in our work, alongside the specimen, was found to be at the same temperature. In these special tests, as in most of the regular observations, the agreement was usually to 1 per cent. The tests and agreements reported are thus entirely favorable.

The furnace, however, was entirely open at the bottom, which presumably caused much greater temperature differences through radiation than there were in our carefully partitioned furnace. The high vacuum should have greatly diminished conduction and convection of heat, leaving heat transfer dependent on radiation. This evidently has a tendency to make the temperatures of inclosed bodies depend more on that of distant objects and on possibly variable radiating power. In Wüst's calorimeter the specimen fell into a metal box with a sheet nickel lid, which, still surrounded by vacuum, rested in a glass tube. The heat transfer was thus probably almost entirely by solid contact and radiation, and would therefore tend to vary with slight changes in the lie of the specimens or in the character of their surfaces, causing variations in the amount of heat escaping upward. In our case the specimen was dropped at once under water, and most of the heat transfer was over in the first minute. Wüst's agreement with the work of others is not very good. For the six metals aluminum, chromium, cobalt, copper, nickel and silver he differs in every case by from 4 per cent to 8 per cent at 100 deg. from Tilden or Schübel, who usually agree with each other to 1 per cent.² At 500 deg. Wüst's discrepancy is less, but compared with specially accurate determinations in the Geophysical Laboratory, his value for silica glass, though high at 100 deg., is 5 per cent too low at 900 deg. He agrees to 2 per cent or better with our value for platinum from 200 to 1,400 deg.

EXPERIMENTAL DETAILS

Several features of the present apparatus and procedure were the same as used in 1908 and later,³ and are

²For a convenient tabulation of their data I am indebted to a valuable résumé of other work given by Wüst himself. In this, however, he compares indiscriminately his own and other results for silica glass ("quartz" glass) with results for crystalline quartz.

already published. Thus: (1) the dropping of the specimen was performed by a mechanical arrangement. (2) The lower partitions were first dropped into a box, the "swinging shield," which was then swung aside by hand to open the path to the calorimeter, and immediately returned to close it against radiation from the furnace. Thus neither furnace nor calorimeter needed to be moved. The motion of the shield operated the dropping mechanism. (3) The use of partitions has been mentioned, and so has (4) the method of eliminating the effect of the heat loss during the drop by subtracting the heat given to the calorimeter by the empty container. (5) The calorimeter temperature was read by a thermel (thermoelectric thermometer) to 0.0003 or 0.00025 deg.;

FIG. 2

Furnace *F*, with partitions, swinging shield *S* and calorimeter with jacket. *FT*, furnace thermel, one platinum-rhodium couple; *CT*, calorimeter thermel, 10 copper-constantan couples; *DC*, cone for directing the falling object also shown, dotted, in position for the drop; *L*, lever for rotating the inner rod in the dropping mechanism; *A*, air space above the water inside the calorimeter; *OC*, jacket cover of sheet copper 0.77 mm. thick; *SH*, cushion. Some supports are not shown. To scale, except that the furnace was 23 mm. higher than here represented.

(6) the thermal head (temperature difference of jacket and calorimeter) was measured directly. This facilitated the use of a calorimetric method which is especially advantageous where the calorimeter is opened to the air at the beginning of the experimental period.

Important differences from the earlier work were:

(1) The furnace chamber was narrower (2.8 cm.), which made for uniformity, though (2) this advantage was neutralized by the fact that the furnace coil was not concentrated at the ends. (3) The falling container was guided by a cone of coarse wire gauze, so that misdirected drops, a great detriment in the earlier work, were entirely avoided, while a smaller opening into the calorimeter could also be used. This cone was attached to the swinging shield and brought into place by it, being out of the way except when the shield was near the position for the drop. Wire gauze was used instead of sheet metal to prevent the reflection of radiant energy from the furnace down the cone into the calorimeter; its use also tended to diminish the amount of cold material touching the hot container in its fall. (4) The calorimeter top was arranged so as largely to prevent loss of heat as the container went into the water. In our earlier work there was merely a device for returning to the calorimeter the bulk of the water thrown up in the splash; the amount of steam produced was slight, and was expected to be fairly constant for a given temperature of the container; such constancy was all that was necessary in the method used. The results obtained with the older arrangement, however, indicated very strongly⁵ that inconstancy in the heat loss at the water surface was the main source of error, sometimes reaching 1 per mille. The manipulation of the splash-restraining device also delayed the closing of the calorimeter. In the present set-up the calorimeter cover, Fig. 2, comes 7 cm. above the water, so that under it is a space of about 1,100 c.c. from which little steam or splash water escapes through the narrow opening which admits the test specimen. This cover is of heavy copper 0.77 mm. thick, so that in temperature it is always practically a part of the calorimeter surface.

The dropping mechanism (Figs. 1 and 2) was simpler and much more compact than that described in 1918, and contained no platinum.⁶ It consisted of a tube of Marquardt mixture 10 mm. in diameter slotted after the plan of a bayonet joint, so as to hold the horizontal platinum wire which was the top of the container hanger, but so as to let this drop when it was rotated into the vertical part of the slot. The rotation was accomplished by a Marquardt rod, slotted at the bottom to take the wire.⁷ Of a number of test drops made outside the furnace, all landed within 2 cm. of the perpendicular after falling 50 cm.

DETAILS OF CONSTRUCTION

The furnace tube, platinum winding and alundum cement used to hold this, all formed a compact tube only 6 mm. in wall thickness. Outside this was calcined magnesia. At the ends were Buffalo fireclay disks

⁵Walter P. White, "Specific Heat Determination at Higher Temperatures," *Am. J. Sci.*, vol. 47, p. 55 (1919).

⁶Marquardt mixture is a remarkably valuable material for structures such as these dropping mechanisms. It keeps its form and enough of its strength indefinitely at high temperatures, probably as high as 1,500 deg.; and when in the form of tubes 2 mm. thick and 10 mm. in diameter can be repeatedly withdrawn from the furnace at 900 deg. without injury. Platinum, however, becomes soft and tends to stretch or loosen at high temperatures, enough so that structures fastened with it rapidly become disarranged and need frequent overhauling.

⁷This mechanism proved the most satisfactory of three that were tried. It was suggested by H. S. Roberts of this laboratory. It could not well have been constructed without a diamond saw. The two others were easier to make. Each had about half of the outer tube ground away for a centimeter or so from the lower end, leaving a projecting lip. In one an inner tube or rod had a notch for the wire; as this rod was rotated the projecting lip pushed the wire free. In the other mechanism the wire rested in notches in the exposed edges of the lip and was pushed out by forcing a Marquardt wedge down the tube. The wedge frequently stuck. A stop is also necessary in front of the notches to keep the wire from leaving one, turning on the other as a pivot, in which case it may drop prematurely or not at all.

⁸Walter P. White, "Some Calorimetric Methods," *Phys. Rev.*, vol. 31, p. 547 (1910).

3 cm. thick. Once when the upper one of these was removed neither furnace temperature (1,394 deg.) nor temperature distribution showed any change exceeding 2 deg. for fifteen minutes. Apparently the disk was a heat distributor as much as a heat insulator. Advantageous modifications of the end construction could doubtless be made.

The furnace stood on an iron plate, which had a hole under the furnace opening. A removable plate closed this hole till the time of the drop. All joints between and above the plates were carefully sealed with asbestos paper or rope, since a very slight upward current of air through the furnace may seriously affect the temperature distribution.

The silica containers were supported by a platinum wire loop passing under the bottom. Small, nearly horizontal, platinum disks at top and bottom still further cut off radiation to the colder furnace ends. The two wires, each 0.6 mm. in diameter, supported over 35 g. for nearly an hour at 1,460 deg. without perceptible stretching.

In order to minimize strain on the somewhat delicate dropping mechanism, the following precautionary features were introduced:

(1) The supporting surfaces along which the wire slid when rotated were not horizontal, but inclined so as to favor turning without causing it.

(2) The rotating force was applied at the end of a rather long (12 cm.) lever, by means of a string passing over a pulley to a weight which fell as a loose piston through a cylinder of water; thus giving a very even motion with little side pressure on the rotating rod.

(3) In preventing rotation during the preliminary manipulations no clamp was applied to lever or tube, but the far end of a rod was fastened whose other end was loosely pivoted to the lever. A suitable stop would probably have been still better.

SUMMARY

By the common method of dropping from a furnace into a calorimeter, the latent heats of nickel and of Monel metal have been determined, and their specific heats for the intervals to 1,360 and 1,260 deg., respectively. The metals were protected against appreciable oxidation by sealing into silica glass containers. The precision of the temperature measurement was studied, and the results indicate a final accuracy of better than 1 per cent. This indication tends to be confirmed by the agreement of all the determinations but one, which was 1.3 per cent divergent. Several determinations were made by pouring directly into the calorimeter nickel just ready to solidify, giving agreement to about 2 per cent with the furnace results. The latent heat of nickel, 73 calories per gram, is 17 calories greater than the recent determination of Wüst. The latent heat of Monel, 68 calories, is in excellent agreement with that of nickel.

The International Nickel Co. furnished material and analyses for this study, and bore part of the direct expense.

Geophysical Laboratory,
Carnegie Institution of Washington.

Lithium Minerals in 1920

According to the Geological Survey, 11,696 short tons of lithium minerals valued at \$173,002 was produced in 1920. Lepidolite from the Stewart mine at Pala, Cal., was used in glass manufacture, while spodumene from the Etta and Swanzey mines, near Keystone, S. D., was used in the manufacture of various chemicals.

Physical Properties of Molybdenum Steel*

BY ARTHUR H. HUNTER

President, Atlas Crucible Steel Co.

MOLYBDENUM steels, as a class, when compared with other alloy steels which are in the same category from a commercial standpoint, treated to the same tensile strength, show:

1. A slightly higher elastic limit, hence a somewhat higher elastic ratio.
2. A higher elongation, hence greater ductility.
3. A much higher reduction of area, hence appreciably greater toughness.

This latter property is probably the most pronounced individual physical result of the addition of molybdenum to steel. From a great deal of data covering these three points, the writer has chosen the following tests, made under the supervision of Dr. J. S. Unger of the Carnegie Steel Co., as exemplifying them in the simplest manner.

Five steels, embracing only the accepted commercial tonnage types, analyzing as shown in Table I, were all heat-treated to give the same tensile strength—i.e.,

TABLE I. ANALYSES

Type of Steel	C	Mn	Ni	Cr	Mo
1. Carbon.....	0.62	0.45			
2. Chrome.....	0.49	0.53		0.60	
3. Nickel.....	0.40	0.65	3.61		
4. Chrome-nickel.....	0.43	0.57	1.60	0.46	
5. Chrome-molybdenum.....	0.32	0.72		0.80	0.27

approximately 125,000 lb. per sq.in. The results were as shown in Table II.

Compared with the carbon steel, the chrome-molybdenum showed 33 per cent increase in elastic ratio, 16½ per cent increase in elongation and 56 per cent

TABLE II. PHYSICAL PROPERTIES

Type	Tensile Strength, lb. per sq. in.	Elastic Limit, lb. per sq. in.	Elastic Ratio	Per Cent Elong. in 2 in.	Reduction of Area, per cent	Red Foot-Lb.
1. Carbon.....	126,175	84,380	66.9	18.0	43.6	5.0
2. Chrome.....	125,300	107,225	85.6	18.0	56.5	66.5
3. Nickel.....	127,975	112,525	87.9	18.8	51.4	54.5
4. Chrome-nickel.....	127,975	111,025	86.8	19.8	60.3	54.0
5. Chrome-molybdenum.....	125,650	112,250	89.3	21.0	68.0	90.0

increase in reduction of area. Compared with the nearest alloy steel, the chrome-molybdenum showed 1.7 per cent increase in elastic ratio, a little over 6 per cent increase in elongation and 12.8 per cent increase in reduction of area. The tensile strength of all these steels having purposely been made the same, the only possible variables were these three.

In direct relation to the foregoing it should be noted that tests by the Izod machine on these steels showed chrome-molybdenum to possess a resistance to impact of eighteen times that of the carbon steel and 34 per cent greater than the nearest alloy steel. As the impact test merely measures the work of rupture under a suddenly applied load, these results, which have been amply corroborated, clearly show the cumulative effect of the higher elastic ratio, elongation and reduction of area for a given tensile strength possessed by the

*Portions of a paper read before the American Iron and Steel Institute, May 27, 1921.

molybdenum steels. Bending tests further bear this out.

In order to give an idea of how the chrome-molybdenum series of alloy steels compares with chrome-vanadium steels, a comparison of two types of each follows. The data on both of the chrome-vanadium steels are taken from a recent booklet published by the Vanadium Corporation of America presenting charts plotted by the metallurgical department of the United Alloy Steel Corporation. The data on both of the chrome-molybdenum steels were furnished the writer by the metallurgical department of the same company. Both series of tests were made on steels manufactured in the open hearth.

TYPE 1—0.40 TO 0.50 CARBON						
Type	C	Mn	Cr	V	Mo	
Chrome-vanadium.....	0.47	0.85	1.19	0.15		
Chrome-molybdenum.....	0.41	0.68	0.95		0.24	
Sections $\frac{1}{2}$ in. round, quenched in oil from 1,560 deg. F. (V) and 1,500 deg. F. (Mo). Drawn to show tensile strengths indicated.						
Type	250,000 lb. T. S.			225,000 lb. T. S.		
	E. L.	El. %	R/A.	E. L.	El. %	R/A.
Cr-V.....	215,400	11.0	38.5	201,000	12.3	42.3
Cr-Mo.....	222,000	9.0	43.5	201,000	10.3	47.9
	175,000 lb. T. S.			150,000 lb. T. S.		
	E. L.	El. %	R/A.	E. L.	El. %	R/A.
Cr-V.....	157,300	15.0	60.5	137,500	17.7	62.8
Cr-Mo.....	163,400	15.5	59.3	141,200	18.7	63.4

It should be noted that the molybdenum content of both of these types of the chrome-molybdenum steel is extremely low. For a comparison on a purely commercial basis steels containing double the above content of molybdenum and showing higher physical properties might well have been used. Considering the lower manganese, chromium and molybdenum contents of the last-mentioned molybdenum steel, a comparison between its properties and those given in the table of Dr. Unger is interesting.

It has been stated above that the physical properties of molybdenum steel were progressively better as the molybdenum content is increased up to 1 per cent, and the table of properties below is presented to illustrate this point:

Sections from which the test-pieces were cut were $1\frac{1}{2}$ in. round or $1\frac{1}{2}$ in. square, quenched in water from 1,550 deg. F. to 1,600 deg. F., drawn to show a tensile strength of 175,000 lb. per sq. in.

ANALYSIS RANGE			
C	Mn	Cr	
0.28 to 0.36	0.44 to 0.64	0.70 to 1.04	
PROGRESSIVE EFFECT			
	Mo 0.20	Mo 0.40	Mo 0.76
Elastic limit.....	167,000	164,000	162,000
Elongation, per cent in 2 in.....	13.5	16.6	19.5
Reduction of area, per cent.....	52.0	58.4	61.0

For a constant tensile strength and very nearly constant elastic limit the ductility of the steel is greatly increased by the addition of molybdenum from 0.20 up to 0.76. Conversely, of course, by employing suitable drawback temperatures, for a given ductility the elastic limit and tensile strength will show an increase in like manner.

The comparative effect of increased section on chrome-molybdenum and chrome-vanadium steels is shown by the following average results on different

sizes of both, taken from test-bars cut from commercial stock:

ANALYSIS RANGE					
	C	Mn	Cr	V	Mo
Chrome-vanadium.....	0.23 to 0.30	0.60 to 0.80	0.70 to 1.00	0.15 to 0.20	
Chrome-molybdenum.....	0.23 to 0.30	0.60 to 0.80	0.70 to 1.00		0.25 to 0.35

EFFECT OF SECTION									
Size	Elastic Cr-V	Limit Cr-Mo	Tensile Cr-V	Strength Cr-Mo	Elastic Ratio Cr-V	Elastic Ratio Cr-Mo	Elongation Per Cent Cr-V	Elongation Per Cent Cr-Mo	Reduction of Area Cr-V
$1\frac{1}{2}$ -in.	134,200	134,800	153,200	156,200	87.6	86.2	16.8	16.8	57.1
$1\frac{1}{4}$ -in.	123,100	132,300	145,500	153,700	84.7	86.3	15.8	16.3	55.8
$1\frac{3}{8}$ -in.	116,900	133,500	150,300	153,200	77.7	87.1	15.1	16.8	53.2
$1\frac{1}{2}$ -in.	103,200	124,600	137,500	152,200	75.3	81.9	14.0	16.3	46.3

The more complex quaternary alloy steels containing molybdenum show extremely high characteristics, as will be seen by reference to the following tables. Both of these steels can be drawn back to better than 1,000 deg. F. before the tensile strength falls below 200,000, and to 900 deg. F. before the elastic limit falls below this figure. The steel containing nickel exhibits remarkable physical properties at low drawing temperatures such as are employed in the production of oil-hardened gears, whereas the steel containing vanadium possesses greater possibilities at the higher drawing temperatures:

	C	Mn	Cr	Ni	V	Mo
Chrome-nickel-molybdenum (1).....	0.44	0.42	0.99	2.04		0.36
Chrome-vanadium-molybdenum (2).....	0.38	0.60	1.00		0.18	0.80
Sections, $\frac{1}{2}$ -in. round (1), quenched in oil from 1,450 deg. F., and $1\frac{1}{2}$ -in. round (2), quenched in oil from 1,600 deg. F., both drawn as indicated.

1,200	186,000	174,000	18.2	59.7

A low-carbon steel to which about $\frac{1}{4}$ per cent molybdenum is added possesses extreme ductility, which makes it particularly adapted in sheet form to the manufacture of pressed steel parts and at the same time when heat-treated is capable of showing fairly high physical properties. Tests made on such a sheet steel test-piece $1\frac{1}{2}$ in. wide by 9 in. long follow. The quenched specimen was cooled in water from 1,600 deg. F. and then drawn to 900 deg. F.

ANALYSIS			
C	Mn	Mo	
0.164	0.45	0.226	
Thickness of Sheet, In.	Condition	Elastic Limit, Lb. per Sq. In.	Per Cent Elongation in 2 In.
$\frac{1}{8}$	As rolled	45,640	44.5
$\frac{1}{8}$	Quenched	120,470	7.5

Molybdenum steels also have the property of deep hardening, especially noticeable in the chrome-molybdenum series. Their properties are developed at higher drawing temperatures than employed with other steels, a fact directly related to their greater toughness and resistance to fatigue.

Dunkirk, N. Y.

Boiler Feed Water Purification

An Outline of the Respective Merits of the Various Methods Used for Boiler Feed Water Treatment, With Special Reference to the Advantages of the Zeolite Water-Softening Process

BY S. B. APPLEBAUM

Assistant Technical Manager, Permutit Company, New York City

THE present-day means used for purifying boiler feed water can be grouped into three distinct classes—namely, boiler compounds, precipitation apparatus and zeolite apparatus. Each of these means has its advocates, and the following outlines the advantages and disadvantages of each and points out which is relatively important and which unimportant, especially from the practical operating viewpoint.

BOILER COMPOUNDS

The use of boiler compounds means the treatment of the water inside the boiler as differentiated from the use of water-softening apparatus which completes the treatment before the water enters the boiler. A great variety of substances have been employed for this internal treatment. Among them may be mentioned soda ash, caustic soda, barium compounds, graphite, tannin, kerosene, slippery elm, glucose, etc. Proprietary secret compounds are usually made up of a mixture of one or more of these substances.

In general, the action of boiler compounds may be divided into two classes:

1. The reduction of hardness by chemical reactions which is exemplified by the use of soda ash and caustic soda.

2. The mechanical action on the scale with the intention of coating the grains to interfere with their close cementation. This is typified by the use of tannin, graphite, slippery elm.

The claims that the action of the second class of compounds was mechanical rather than chemical had a certain appeal to the operating engineer, to whom chemistry has been and still is somewhat of a mystery. The general failure of such compounds to fulfill the fantastic claims made for them has imparted an unscientific atmosphere to the field of internal boiler treatment.

The nature of the chemical reactions with the feed water, however, when boiler compounds of the first class are used is in the same general class with those involved in a precipitation water-softening plant. The important difference is that the precipitates formed by the reactions with the boiler compounds enter the boilers, whereas in the case of the precipitation water-softening plants the precipitates are removed from the water by settling and filtration, only the clear softened water entering the boilers.

The boiler compound advocate makes three claims: First, that the resultant precipitates form a sludge inside the boilers less compact than the scale formed by the hard water and that therefore the first cost or investment in settling tanks and filters may be saved by using the boiler itself as a settling basin. Second, more accurate proportioning of the chemicals is accomplished than in precipitation plants. Third, boiler com-

pounds save the loss of water wasted in washing filters and sludging off settling tanks of precipitation plants.

In answer to these claims the following considerations must be taken into account:

Sludge in a boiler will accumulate and will bake together into a hard layer and the reagents added in general increase the amounts of deposits and the burden of solid content which the boiler has to bear. To maintain the high boiler efficiency to which modern power plant practice has attained, it is essential to maintain the heating surface absolutely clean both inside and outside. It is just as necessary to prevent sludge accumulating on the wet side of the heating surface as it is to keep soot off the dry side. If efficiency is not a consideration, if labor for cleaning is negligibly cheap and if fuel be plentiful and extremely low in price, then the use of boiler compounds may be permitted, but these conditions, although they may have been found formerly, no longer exist today.

Regarding the second claim, of greater accuracy of proportioning, this is difficult to substantiate. The same problem exists in both cases of adding definite amounts of certain chemicals in accordance with the composition of the incoming water and also to proportion the volume of chemical solution to the volume of water to be treated. A general inspection of the usual boiler compound feeding devices and of the precipitation plant chemical feed controls will disclose a contrast in favor of the latter from the point of view of refinement, mechanical ingenuity and reliability of action. Furthermore, it is possible to check up the results of treating a water in precipitation water softeners by analyzing the effluent before it enters the boiler and so adjust the treatment until the desired results are obtained. By using boiler compounds it is possible to check up on the efficacy of the dosage only by inspecting the boilers after they are taken "off the line."

The third claim is correct, but offsetting it is the loss of heat in the water blown off from the boiler. If the boiler is to receive the precipitates, and the sludge formed by the boiler compound is not to accumulate, it must be blown off. The heat lost in the blowoff water above 250 deg. F. required to sludge off the boiler is one of the most serious penalties incurred by the use of the boiler itself as the precipitation tank.

PRECIPITATION WATER SOFTENERS

Precipitation water softeners embody the main principle of adding prescribed amounts of definite soluble chemicals, usually lime and soda ash, to react with the hardening compounds of the raw water.

There are two main divisions of precipitation plants—namely, intermittent and continuous. The former consists of two or more settling tanks, one filling and receiving its charge of chemicals while the other is

being used to deliver treated water to service. In this way each tank goes through a cycle of operations—filling, charging, agitating, quiescent settling and finally emptying. The continuous plants usually have one settling basin, and the water flows continuously from inlet to outlet, receiving the charge at the inlet, settling as it flows and after filtering leaves at the outlet completely treated.

Intermittent plants are preferred for the treatment of waters which vary in composition between wide limits because the average composition of a tankful of water can be determined irrespective of the variations that may have taken place as the tank was being filled.

Some continuous plants have heaters ahead of the settling tanks and permit the reactions and settling to take place at boiling temperature. Although this gives a resulting effluent of lower hardness and a smaller settling tank is permissible because of more rapid reactions, the loss of heat by radiation from the settling tanks and filters and also by losing hot water in sludging off and washing of filters must be considered.

ZEOLITE WATER SOFTENERS

Zeolite plants accomplish the removal of the hardness by percolation of the water through a bed of zeolite material suitably supported and distributed in a closed or open container with piping and valves attached to the container properly to distribute and control the flow of water. The hardness is removed from the water by the well-known zeolite exchange principle, the zeolite exchanging its sodium base for the calcium and magnesium bases in the water. A meter is provided to indicate when the softener has passed the quantity of water it was designed to soften. The zeolite bed is then automatically regenerated or revived by passing a solution of salt (common brine) through the softener. The brine, by a reversed exchange reaction, gives its sodium base to the zeolite, and as it leaves the softener it carries with it in a clear solution the calcium and magnesium extracted from the zeolite. Where 24-hr. operation is required, one softener treats the water while the other is regenerated and they are consequently switched at proper intervals to provide continuity of operation. A tank is provided to make the brine and its flow to and from the softeners is automatically accomplished by properly designed equipment which forms an integral part of the modern zeolite softener. The zeolite is then rinsed free of brine and the softener is again thrown into service by opening the necessary valves.

SPACE REQUIRED FOR WATER SOFTENERS

For cold-precipitation plants it is customary to allow a minimum of four hours for the reactions to take place and the precipitates to settle. This means a tank or basin holding four hours' supply of water. For a capacity of 10,000 gal. per hour a 40,000-gal. tank would be required, say 15 ft. in diameter by 32 ft. high. This is generally too large to be accommodated in existing buildings. It must be located outside and thus involves extra land, foundations and housing, all of which should be added to the cost of the apparatus when making comparisons.

Zeolite plants accomplish complete removal of the hardness in several minutes; for example, a water of 10 grains of hardness per gallon is softened to zero hardness in approximately ten minutes. For a capacity of 10,000 gal. per hour and for an average water of 10

grains per gallon of hardness a zeolite softener 10 ft. in diameter by 10 ft. high would be required. This can usually be housed in an existing room, thus saving land, special foundations and extra housing.

Precipitation settling tanks or basins are open, and it is therefore generally necessary to install additional pumping equipment.

Zeolite plants can be and generally are built to withstand existing water pressures and the water passes through the softeners to service without the need for additional pumps. This not only saves initial investment but saves an appreciable operating charge.

OPERATION OF PRECIPITATION WATER-SOFTENER PLANTS

In the operation of precipitation plants, it is necessary to make a chemical analysis of the raw water and a determination of the purity of the chemicals in order to calculate the correct charge of lime and soda ash or other reagents to react with the varying composition of the raw water. Many water supplies are drawn from surface sources such as rivers or ponds. The volume of water in these supplies varies with the seasons and with the rainfall. Sudden storms have been known to change the mineral content of a stream completely in a few minutes. If too little chemical is added to the water the hardness is incompletely reduced and if too much chemical is added an objectionable amount of the excess of chemicals is left in the treated water. The addition of too great an excess of lime may even form a harder water than the original supply, since lime, besides being caustic, is also a form of hardness. The writer has analyzed samples before and after several precipitation plants where this condition was found to exist. The operator must therefore be alert and skilled to control the treatment properly.

Besides the need for skilled supervision to apportion the chemical dosage to suit the composition of the raw water, there are various mechanical problems to solve. Sludge disposal from the settling tanks frequently clogs sewers and some city ordinances prohibit dumping sludge into sewers on this account. This frequently entails sludge collection in pits and removal by digging out periodically and carting away to disposal dumps. The mechanical problem also exists of feeding the chemicals at a rate in proportion to the rate of the raw water flow. This involves a form of meter for the water and a meter for the chemicals. Since the chemicals are usually fed in the form of a suspension of particles or a milk, the meter itself may become coated with the particles, with a resultant change in the rate of chemical dosage. The complexity of this chemical feed problem from the mechanical point of view is evidenced by the many hundreds of devices that have been developed and patented to date.

OPERATION OF ZEOLITE WATER-SOFTENER PLANTS

The operation of zeolite water softeners marks a radical departure from the precipitation process. The water is distributed uniformly through the bed contained in the zeolite apparatus and in its passage through the bed of zeolite the hardness is completely removed, the calcium and magnesium entering the grains of the zeolite by chemical exchange for the sodium which the grains give up to the water. No sludge is formed and no problem of sludge disposal exists. No chemicals are added and the mechanical problem of controlling the feed of chemicals is avoided. The zeolite, an insoluble reagent, reacts completely with the relatively

small quantity of the salts of calcium and magnesium in the water.

This zeolite exchange principle or reaction is of universal occurrence in the fertilization of soils where the soil absorbs the potassium salts from the fertilizer by a similar chemical exchange.

The fact that the zeolite is insoluble makes possible this complete removal of the hardness from the water without the possibility of there being an excess of reagent in the softened water. The volume of the zeolite used is greatly in excess of the theoretical quantity required for the reaction and thus by mass action drives the chemical exchange—i.e., the softening action—to the end point of zero hardness water.

Slight amounts of hardness in the effluent of some zeolite softeners have been noticed in some cases;¹ but this can mean only that the particular zeolite softeners examined were improperly designed and that the volume of a proper grade of zeolite used was not in sufficient excess so that the softener was seriously overloaded.

If a zeolite softener is greatly overloaded it acts exactly as most mechanisms and structures used in engineering work under excess load. If precipitation water-softening plants are overloaded, the reactions are not completed in the settling tank and the resulting precipitates collect in the outgoing pipe lines, heaters, boilers, etc. A zeolite softener has a definite duty to perform, and if that duty is seriously exceeded the worst possible effect that can result is the production of a water with a slight residual hardness. If the size of the zeolite softener is correctly selected to take care of the required volume of water containing a known hardness, the effluent of the softener is always of zero hardness.

The capacity of a zeolite softener plant varies approximately in inverse proportion with the hardness of the raw water. If the zeolite apparatus is properly designed to take care of the owner's requirements of volume of water and hardness of raw water this is the most notable of advantages.

RELATIVE RESULTS OBTAINED IN PRECIPITATION AND ZEOLITE WATER-SOFTENER PLANTS

Precipitation plants reduce the hardness of the water to 4 to 5 grains per gallon in the cold, and 2½ to 3 grains at boiling temperature. The reason for these limitations is to be found in the character of the reagents used and in the resulting reactions. In order to drive any chemical reaction to its limit an excess of the reagents is required. But since lime and soda ash are soluble reagents, this excess is found in solution in the treated water, and if too great, renders the treated water unfit for industrial or domestic use. Furthermore, some waters offer great resistance to the action of reagents. The resultant precipitates, calcium carbonate and magnesium hydroxide, sometimes form very slowly and remain in a colloidal condition and thus slip through the filters into the service lines. In the *Engineering News Record* of Jan. 13, 1920, this colloidal condition is reported in connection with the municipal precipitation plant of the City of Columbus, Ohio. A hardness of 100 p.p.m., or 6 grains per gallon, was found present in the softened water as a result of this colloidal condition. The precipitates themselves are also soluble to the extent of several grains per gallon,

so that it is theoretically and actually impossible, even if the reactions could be driven to completion, to produce zero hardness water by the precipitation process.

Zeolite plants produce zero hardness water because the zeolite is insoluble and a great excess may therefore be employed without appearing in the softened water.

COMPARATIVE COST OF OPERATION OF PRECIPITATION AND ZEOLITE WATER-SOFTENER PLANTS

The relative cost of the reagents used in the treatment by the precipitation and zeolite processes depends on the local market prices of hydrate of lime, soda ash and salt and also on the composition of the raw water.

The market prices today average about 1c. per lb. for hydrate of lime; 2½c. per lb. for soda ash and 1c. per lb. for salt. One pound of hydrate of lime added to 1,000 gal. will react with about 8 grains per gallon of temporary hardness. One pound of soda ash added to 1,000 gal. will react with about 6 grains per gallon of permanent hardness. One pound of salt will regenerate a volume of zeolite that has softened a thousand gallons of water containing about 2 grains per gallon of either temporary or permanent hardness. Therefore for temporary hardness: 1 lb. lime at 1c. reacts with 8 grains, or about 12c. per grain; 1 lb. salt at 1c. reacts with 2 grains, or about 6c. per grain. Lime treatment is therefore half as costly as zeolite softening for temporary hardness. For permanent hardness: 1 lb. soda ash at 2½c. reacts with 6 grains, or about 4c. per grain; 1 lb. salt at 1c. reacts with 2 grains, or about 2c. per grain. Soda ash treatment is therefore twice as costly as zeolite softening for permanent hardness. Waters therefore which contain equal amounts of temporary and permanent hardness can be treated at the same cost by either method. But as the permanent hardness rises in proportion to the temporary hardness present softening becomes more economical by the zeolite process.

In making the above calculations no account has been taken of the fact that softening with lime and soda ash leaves 4 to 5 grains of hardness in the treated water. For example, if the raw water has an average of 14 grains per gallon of hardness, of which 8 grains may be temporary and 6 permanent, the lime and soda ash cost of treatment is about 3½c. per thousand gallons. But if 4 grains are left in the soft water, only 10 grains have been removed, so that per grain of hardness removed the cost is 0.325c. The same water would be totally softened by the zeolite process for about 2.8c. per thousand gallons, which establishes a cost of 0.2c. per grain of hardness removed.

CASES WHEN THE COMBINATION OF THE PRECIPITATION AND ZEOLITE PROCESSES IS ECONOMICAL

Waters containing extremely high amounts of temporary hardness—for example, more than 25 grains per gallon—and at the same time containing relatively low amounts of permanent hardness—say, less than 10 grains per gallon—are economically treated as far as cost of chemicals are concerned by using lime and soda ash, but if in such cases the volume of water to be treated is fairly large the most economical treatment is obtained by combining the precipitation and zeolite processes, using the lime to reduce the temporary hardness and the zeolite to remove the permanent hardness and to finish the incomplete work of the lime. Thus one can select what is advantageous from both processes and at the same time produce a water of zero hardness.

¹"A Comparison of Various Methods of Water Purification," W. M. Taylor, CHEM. & MET. ENG., vol. 24, No. 3, Jan. 19, 1921, p. 123.

The precipitation plant reduces a portion of the hardness and the pretreated water then passes to the zeolite plant, where the work of softening is completed. This also insures the reduction of the total solids of the water by the precipitation and removal of the greater part of the bicarbonates or temporary hardness. A number of combined lime-zeolite plants of this nature have been in operation in the United States for years.

RELATIVE INFLUENCE OF VARIOUS FACTORS ON FOAMING

It is falsely claimed that zeolite softened water increases the tendency of boilers to foam, on the consideration that the sodium salts have a heavier molecular weight by about 5 per cent than the corresponding calcium or magnesium salts. This is a chemical super-refinement inasmuch as the blowoff from the boilers maintains concentrations of total solids in the boiler salines considerably below the foaming concentration limit so that variations of 5 per cent in the total solids of the feed water are negligible by comparison.

Offsetting this possible 5 per cent increase in total solids is the very important fact that the water in a boiler fed with zero water is clear and free from particles of suspended scale and sludge or mud. And experience proves that the tendency to foaming is greatly increased by the presence of such suspended matter. This is illustrated also by the fact that when scaled boilers are suddenly fed with softened water, the scale which is loosened by the action of the soft water forms just such a suspension of particles and for a short period foaming is experienced. As soon as the boilers are thoroughly clean, however, they remain clean thereafter and the water inside the boiler clears up and the foaming ceases. A regular blowoff schedule can then be worked out to suit the operating conditions of the boilers in question, taking cognizance of the steam disengaging velocity and design of the boiler, all of which influence the limiting concentration of the boiler salines. Testing blowoff water with standard hydrometers should also be made standard practice to check up on the blow-off schedule.

Oil, organic and saponifiable matters are especially provocative of foaming. This is illustrated by a plant in Ohio using zeolite softened water in Sterling boilers of 1,000 h.p. total at high ratings with a water containing 25 grains per gallon total solids. No foaming was experienced during the summer on 100 per cent makeup, but in winter, when returns of 50 per cent from a heating system were used, foaming was observed. The returns lowered the solids in solution, but contained oily sludge previously deposited. As the heating system cleared up, this winter foaming disappeared.

NEED OF ZERO HARDNESS BOILER-FEED WATER

It is sometimes claimed that a feed water containing as much as 4 to 5 grains of hardness per gallon does not form a sufficient deposit in boilers to warrant consideration. Practical experience, however, proves that such a water is not satisfactory for boiler-feed purposes. When the statement is made that boiler compounds are good enough, that statement is linked with the past when the United States was an agricultural and not an industrial nation. Our national power requirements demand the highest degree of power plant operating efficiency. The time has passed when coal and oil were cheap and could be wasted. The recent war has demonstrated the ever-growing scarcity of fuel and the importance of conserving our natural resources.

The tendency today is toward boilers of ever-increasing size up to 1,000-hp. units operating with automatic stokers, at 200 to 300 per cent of normal rating and at very high pressures and superheat. This has developed an entirely new set of conditions.

Higher temperatures are being produced in the furnaces and far greater quantities of heat are being transmitted through the heating surfaces. Therefore greater care must be exercised in keeping the heating surfaces as clean as possible to avoid all danger of overheating the metal. Such immense boilers cannot be thrown off the line for repairs with the ease of former days. They are expected to run continuously for considerable periods without shut-down. What was good enough ten years ago with small boilers at low ratings, low pressure and low efficiency can no longer be countenanced. A water containing 5 to 6 grains per gallon of hardness in a 1,000-hp. boiler running at 300 per cent rating deposits in one day 220 lb. of scale on the inside of the boiler. In ten days more than a ton of scale would coat the heating surfaces. This certainly is not "good enough." The limit of hardness in the feed water must obviously come down to zero.

The Association of Central Power Plant Operators gave its opinion on this point in *Power* for June, 1916, in describing the results obtained from a water softener in a large central power station in New York operating on New York City's supply of 2 to 3 grains per gallon:

The results obtained develop a fact that is of great interest—that scale will form where boilers are operated at such high rating as 200 per cent—if the water contains a hardness such as is usually obtained in the average water-softening plant. That is, boilers will not be free from scale if fed with a water of 4 grains hardness; therefore a greater refinement must be obtained to meet this condition. The demand for 200 per cent rating is growing as more and more plants are being built to operate at that rating and greater care will have to be taken to put into such boilers water containing the least possible hardness.

CONCLUSION

In conclusion, the use of boiler compounds for the treatment of boiler-feed water can no longer be recommended in view of the disadvantages resulting from this internal boiler water treatment. The recent demand for increased efficiency for boiler plants, the increase in the size of the boiler units being put into operation, and the tendency which has developed of increasing the rating at which the boilers are operated, make it especially necessary to keep the boilers free from any deposits. These same developments in boiler-operating practice have also created an unmistakable demand for a water as free from hardness as can be produced in order to maintain the heating surfaces perfectly clean.

The design of a water-softening plant to produce this zero hardness water depends on the composition of the raw water. If the hardness of the raw water is predominantly temporary in character and the amount of water to be treated is fairly large, the most economical type of treatment is the combination of lime-precipitation followed by zeolite water softening. If the proportion of the temporary hardness in the raw water is much below the proportion of permanent hardness present, straight zeolite treatment is to be preferred.

Frequently also, irrespective of the composition of the raw water, a preference has been clearly found to exist for the straight zeolite treatment due to its simplicity, certainty of action and freedom from the problem of sludge disposal, chemical feeding and after reactions common to precipitation water-softening plants.

Forest Products Laboratory Plans Work for the Year 1921-22

AS RECENTLY noted in the news columns of CHEMICAL & METALLURGICAL ENGINEERING, the appropriation for the coming year allotted to the Forest Products Laboratory, Madison, Wis., has been increased \$100,000 for the year 1921-22.¹ New activities have been planned in the carrying out of research along present lines as noted in the following paragraphs:

WOOD MANUFACTURING WASTES

Of new work greatest emphasis will be placed on investigations to reduce the waste of two-thirds which now occurs in manufacture between the standing tree and rough, seasoned lumber, and of the further waste of from 10 to 15 per cent or even more in the remanufacture of rough lumber into final products. This means that approximately 75 per cent of the volume of every tree cut is wasted in manufacture before the final product is reached. High lumber prices and shortages of many important species of wood have made the question particularly acute.

The first phase of the problem to be undertaken will be to determine the possibility of cutting what is called dimension material—i.e., the exact sizes to be used in manufacture—direct from the log for furniture makers, wood turners and many other industries rather than first into lumber. For example, it is reported that in the manufacture of hickory handles two tons of material in the form of lumber is sometimes required to produce 400 lb. of handles, and in the furniture industry from 40 to 60 per cent of the lumber purchased is lost in various stages of manufacture. It is believed that manufacture directly into dimension material will materially reduce this waste. A systematic survey of waste which occurs in wood-using industries as contrasted with requirements will be undertaken in order that a market may be found in some industries for the waste in others. This is an exceedingly complex problem with great opportunity for saving. The possibility of a uniform system of lumber grading to replace the present multiplicity of systems will be studied in the interest of greater simplicity for the consumer, and second, to make possible the effective application of strength data, particularly in connection with municipal building codes.

PULP AND PAPER

Pulp and paper investigations will also be extended. Present processes employed in producing chemical pulps, which now use nearly 4,000,000 cords annually, convert less than 50 per cent of the raw wood into paper. An attempt will be made through research to reduce this enormous waste. Preliminary experiments indicate that increased yields can be obtained and that the wood now wasted can be saved and valuable chemical constituents reclaimed. Other preliminary investigations indicate the possibility under a modification of the sulphate pulp process of producing book and other high-grade paper from such resinous woods as Southern pine. The high prices now being paid by publishers and the great economic importance of making possible the utilization of a large amount of material now wasted justify this work on an enlarged scale. Fully \$5,000,000 worth of pulp is now lost annually by decay and a still

greater value of pulpwood decays through improper methods of handling. Investigations already under way to reduce this decay should be enlarged and continued. Twenty-thousand dollars of the proposed increase is needed for these urgent pulp and paper problems.

TIMBER TESTING

In timber testing it is desired to take up the development of methods for built-up and laminated construction, which offer great possibilities of utilizing small sizes and material now waste or of little value. Success for such articles as wagon parts and structural members depends upon comparative strength and permanence as compared with solid pieces, the development of improved glues or other satisfactory methods of fastening and a general industrial modification of existing standards and practice. The work is of particular urgency at the present time because of high prices and scarcity of high-grade material, and the difficulty in securing many kinds of timber formerly common.

The testing of large-sized columns will be undertaken. No data are now available on the strength of such columns, and it is necessary for safety to use considerably larger sizes than would be required if accurate strength data were available. A large amount of additional testing is necessary on wooden boxes and crates and fiber containers. The \$55,000,000 paid by the railroad companies in 1918 in claims resulted largely from faulty containers, and this is only one phase of the loss from this cause for which the consumer pays. Tests are needed on a large number of containers representative of different classes of commodities. Also, the fundamental relationship of kind and thickness of wood, nailing and strapping of the container to the size and weight of the contents will be investigated. Such data will have an almost universal application in placing boxing, crating and packing on a sound technical basis.

WOOD DISTILLATION

Chemical utilization offers probably the greatest opportunity of utilizing wood waste. In addition to work on pulp and paper problems, that on the manufacture of ethyl or industrial alcohol should be enlarged. Several millions of gallons of ethyl alcohol is now manufactured annually from wood in two plants in the United States. Investigations by the Forest Service have reduced operating costs at the larger of the two plants by 9c. a gal., and were an important factor in its success. Ethyl alcohol manufacture is important as a possible means of utilizing sawdust in mill waste, and the process offers a possible substitute for gasoline as fuel if through research production costs can be sufficiently reduced and manufacture made possible at small plants with low assembling costs. Investigations of hardwood distillation have increased the number of species which can be utilized from three to eight, have shown how without increasing operating costs yields of acetic acid and methanol can be increased 15 per cent, and more recently have shown how yields of methanol can be increased on an experimental scale by 50 per cent through the addition of one chemical. Since methanol can be obtained only from the distillation of wood, is essential in many basic chemical industries and can be made to utilize low-grade wood unsuitable for other purposes, the enlargement of investigations of this character is exceedingly desirable.

¹See CHEM. & MET. ENG., March 30, 1921, p. 579.

Finally, much of the progress in all investigations of chemical utilization of wood will in the future depend upon a more advanced knowledge of the chemistry of wood. Additional work will therefore be undertaken into the fundamental chemistry of wood and its principal groups of constituents. The findings will be of immense value in pulp and paper making as well as in

all of the other chemical industries which use wood as a raw material.

DRYING RESEARCH

Improved methods of drying designed to reduce the largely unnecessary annual \$50,000,000 loss in the seasoning of lumber have been developed on thirty-five woods, including Douglas fir, Southern pine, spruce,

Fig. 1. Temporary quarters of timber testing department—The demands for information from the Forest Products Laboratory have been so great that this temporary building, formerly used as a war training barracks, was occupied. The tower in the foreground houses the 1,000,000-lb. universal testing machine recently installed. The double doors on either end can be opened to allow the testing of large members. Columns 30 ft. long and 12 in. square can be tested to destruction in this machine.

Fig. 2. Testing wood at a known moisture content—The strength of wood varies with the moisture content and the density (dry weight) of the piece. The importance of these two laws has been fully established by more than 500,000 separate tests of wood samples at the U. S. Forest Products Laboratory, Madison, Wis. From these tests and other data the density rules for grading Southern yellow pine and Douglas fir structural timbers were developed. This density rule provides a visual method of estimating the density of wood by relative proportions of springwood and summer wood (hard-growth rings and soft-growth rings) that shows on the end of a stick. The man in the foreground is marking a tested specimen for the moisture determination to be made by the girls in the immediate background. Moisture content is the difference between a given moisture condition and the oven-dry weight. The moisture content is dependent upon the atmospheric conditions of the place where the wood is stored.

Fig. 3. Erecting a million-pound testing machine—This million-pound capacity universal testing machine is to be used in studying full-size timbers. The influence of defects, such as knots, on strength is one of the important investigations contemplated. Columns 30 ft. long and 12 in. square can be tested to destruction in this machine. The part of the machine on which the man at the left is standing weighs 12 tons. The whole machine weighs 80 tons. The machine is of universal type, making tension and compression tests with equal facility.

Fig. 4. Experimental paper machine—This miniature machine can turn out a 16-in. strip of paper at the rate of 40 ft. a minute. It is equipped with both Fourdrinier and cylinder wet ends and it is used in determining the paper-making qualities of native woods. Such information is urgently needed at present on account of the rapidly diminishing supply of the woods commonly used for the manufacture of paper pulp.

gum and many of the oaks. Further improvement in methods must come through the determination of the limitations and possibilities of present types of dry kilns and their improvement, a wider knowledge of essential drying conditions for all our woods, and research into such fundamentals as the relation of moisture in the natural laws which govern the seasoning of wood. Present losses are an added production cost and also a wholly unnecessary drain on our forest resources, most of which can be eliminated by research.

WOOD PRESERVATIVES

Further work is also planned on the development of various classes of wood preservatives. There is a large loss of timber in wharves, docks, etc., caused by marine borers. It is now possible to study the activities of these borers and to attempt the development of the preservatives only in the San Francisco Bay region, where conditions are particularly acute. The study will soon be extended to cover other points on the Pacific, Atlantic and Gulf coasts.

Efforts will also be made to develop a cheap, odorless preservative against wood decay suitable for wood used in exposed situations in such structures as houses, which will take paint and which can be supplied in quantity.

The accompanying photographs and descriptions give some idea of the equipment at the laboratory available for this work.

Cadmium in 1920*

BY C. E. SIEBENTHAL AND A. STOLL

THE production of cadmium, either as the metal or as the sulphide, has been reported by the companies in the following list, which shows also the nature of the metallurgic plant in connection with which the cadmium plant is operated:

PRODUCERS OF CADMIUM IN THE UNITED STATES IN 1920

Company	Location of Plant	Associated Plant
American Smelting & Refining Co.	Denver, Col.	Lead smelter
Grasselli Chemical Co.	Cleveland, Ohio	Chemical works
Krebs Pigment & Chemical Co.	Newport, Del.	Lithopone plant
Midland Chemical Co.	Argo, Ill.	Lithopone plant
U. S. Smelting, Refining & Min. Co.	Kennett, Cal.	Electrolytic zinc plant
U. S. Smelting, Refining & Min. Co.	Midvale, Utah	Lead smelter

Of these the plant at Kennett, Cal., was reported to have made no output in 1920. The lead furnaces at the Globe plant of the American Smelting & Refining Co., at Denver, have been closed for some years, but stocks of cadmiferous residues remain from former operations and more has been shipped in from other plants of the company.

MANY PLANTS HAVE PROCESSES FOR RECOVERING THE METAL

Several other electrolytic zinc plants and lithopone plants save cadmium-bearing residues and have worked out processes for recovering the metal, so that an extension of the uses of cadmium and an increased demand for it would result in additions to the list of producers. Several companies that produce cadmium-bearing residues sell them to the producing companies named above.

In 1918 a canvass was made of lead smelters, electrolytic zinc reduction and refining plants, lithopone plants, and a few typical brass works, with the object

of ascertaining the yearly recovery of cadmium in fumes and residues, the accumulated stocks of such materials, and the maximum yearly capacity of the cadmium-reduction plants.

CADMIUM ACCUMULATING

According to the data obtained, cadmium is accumulating at lead smelters at the rate of 350 to 400 short tons annually, and the stocks of bag-house fumes contained more than 750 tons of cadmium. At electrolytic zinc plants about 200 tons is accumulating annually and the stocks of residues contained about 400 tons. At lithopone plants probably 50 tons is produced annually and about 25 tons was contained in stocks. In round numbers, then, 600 short tons accumulates annually, and there was on hand in 1918 approximately 1,200 tons in stocks of fumes and residues. Not all the stocks are rich enough for the cadmium to be commercially recovered, but perhaps material that carries 1,000 tons is suitable for treatment. The average recovery of cadmium is about 75 per cent. We may therefore estimate that 750 tons of recoverable cadmium in residues was in stock in 1918. At some electrolytic zinc plants the cadmium in the residues is wasted in recovering copper and lead.

CAPACITY FOR METALLIC CADMIUM

The maximum capacity for metallic cadmium reported by producers is 29,000 lb. a month, or about 175 tons a year. If the price of cadmium and the demand for it should justify expansion the producing capacity could no doubt be brought up with reasonable promptness to 500 short tons or more yearly. The price of cadmium will be the deciding factor also in determining what grade of cadmium fumes can be worked at a profit.

USES FOR CADMIUM

The alloys of cadmium most generally used are the easily fusible alloys used in the tips of automatic sprinklers, in safety plugs for boilers and in electric fuses; cadmium cliché metal for stereotype plates, and solders in which cadmium is substituted for part or all of the tin commonly used.

A fraction of 1 per cent of cadmium is used as a deoxidizer in making bronze telegraph and telephone wires and cables in France and Italy. The larger part of the cadmium exported from the United States goes to France. Cadmium is also used as a deoxidizer in making nickel alloys and may serve a like purpose in making brass.

A newer use for cadmium is in making small-arms ammunition. A cadmium band on the hard-jacketed cartridge ball takes the rifling with little wear on the barrel and thus prolongs the life of the gun.

ELECTROPLATING OFFERS PROMISING FIELD

Cadmium electroplating is a field that offers some promise of expansion. Cadmium is a better rust preventive than nickel, and at more nearly a parity in prices cadmium plating might be substituted for nickel plating on some articles. Or, as it has a greater tendency to tarnish than nickel, it might be used in combination with nickel, the first coat consisting of the rust-preventive cadmium and the second coat of the tarnish-proof nickel.

The Udyllite Process Co., of Kokomo, Ind., has developed a commercial method for electroplating iron and steel articles with cadmium and is prepared to grant licenses for its use.

Heat-Treatment of High-Speed Steel Cutting Tools of Intricate Design

BY A. J. LANGHAMMER

MODERN manufacturing methods, especially where the principles of quantity production are applied, demand tools capable of continuous heavy duty performance. High-speed steel is the natural material from which such tools are made, and this article is limited thereto. Big production methods necessitate huge supplies of cutting tools. The specific type the writer has in mind is such cutting tools as taps, threading dies, hobs, broaches and special form cutters.

Attention is invited to the included photographs, Figs. 1, 2 and 3, of three special cutting tools. By an inspection of Fig. 2 it is at once obvious that any defect in the curved cutting edges greatly reduces the service of the tool, if it is not totally destroyed. In Fig. 1 this is not true to such a great extent. However, it is well known that no consumer will accept defective tools. Fig. 3, on the other hand, illustrates a type in which the tool hardener has little or no leeway. Such defects as pitting, deformation, dull or crushed edges absolutely incapacitate the tool. The importance of correctly heat-treating special cutting tools is therefore readily seen.

The machining of such special cutting tools offers no great difficulties—it is only in the hardening where trouble begins. In tool shops and large industrial

design made from the same brand of steel and even the same bar, where all precautions were taken to eliminate the variables affecting cutting speed and the only factor not a constant was that of the hardening method. Results have convinced him that the open-fire hardening method was undoubtedly the best, whenever the necessary care and skill was applied.

The reason for this is that in pack-hardening the temperature to which the tool is subjected is pure guesswork and is practically beyond control. Then, too, we have that important element—the time factor. When we consider that the heat-treatment of high-speed steel calls for a preheat of 1,450 deg. F. or thereabout, and then a *rapid heating* to exactly the "sweat point," the above statement is easily substantiated. Discoloration is somewhat under control by the tool hardener, and different brands of steel "clean up" better; however, pack-hardening generally gives a cleaner job, although with the open-fire method slight polishing, pickling, or sand blasting after quenching gives a superior product.

It should be noted, moreover, that the hardening of cutting tools of intricate design by the open-fire method is the acme of high-speed tool hardening. Only with the very best of care and closest attention are excellent results obtained. It is for this sole reason that the pack-hardening process was ever brought into practice. When the open-fire method is used, it is necessary to have a rich flame and all possibilities of oxidation must be eliminated. The temperature must be closely ob-

SPECIAL CUTTING TOOLS

plants one or both of two general hardening methods are used—i.e., "pack-hardening" or "open fire." By open fire is meant any method employing a muffle, or semi-muffle furnace, or a blacksmith's forge. Pack-hardening, of course, is used in the sense that is always understood, the packing material being carbonaceous material.

The following advantages are claimed for each method by their proponents, and it will be noted that they are practically identical:

PACK-HARDENING	OPEN-FIRE HARDENING
1-a—No scaling or pitting.	2-a—No scaling or pitting.
1-b—Little or no deformation.	2-b—Little or no deformation.
1-c—Absence of objectionable discoloration.	2-c—Maximum hardness (red-hardness).
1-d—Preserving of original sharp cutting edges.	2-d—Preserving of original sharp cutting edges.
1-e—Uniformity of product.	2-e—Uniformity of product.
1-f—Better cutting qualities.	2-f—Better cutting qualities.

For a number of years the writer has had occasion to observe the performance of cutting tools of intricate

served, and the tool quenched just before the "sweat point" is reached. The transfer of the tool from the furnace to quenching tank or lead pot must be quickly executed. Care must be exercised that no obstruction is met in the transfer, as the least impact will destroy the cutting edge. When this is done, the advantages listed as 2-a, 2-b, 2-d, 2-e and 2-f are obtained and in addition the most desirable one of maximum red-hardness. The writer has met one or two tool hardeners who regularly achieved good results with pack-hardening because of their uncanny skill. But this is the exception that merely proves the rule.

When an intricate cutting tool is correctly hardened by the open-fire method, it will permit greater cut speeds, longer periods between regrinds, produce a finer product, give a greater life, and therefore will yield a bigger production at reduced factory costs.

Legal Notes

BY WELLINGTON GUSTIN

Non-Delivery Under Installment Contract Not Justified by Non-Payment for Past Delivery

The liability of a manufacturer for failure to deliver agreed installments under a contract was the subject of an action before the Court of Appeals of Georgia, *Smith versus Harrison et al.*, 106 S. E., 191. The court's rulings and holdings were substantially as follows:

In a contract of sale an obligation by the seller to deliver to the buyer by a certain date a gross quantity of a certain product for a certain estimated price, as 1,000 gross of glass containers at some agreed rate per gross, but which must be delivered in certain stipulated quantities periodically at certain designated periods, is entire, and a failure by him to make any one of the deliveries at the time agreed upon amounts to a breach of the entire obligation and gives to the buyer the right to elect to bring suit before maturity for such damages as he may have sustained by reason of such breach. (*Phosphate Mining Co. vs. Atlantic Oil & Fertilizer Co.*, 93 S. E., 532.)

In such an action the buyer may recover such damages as he would have sustained by non-performance by the seller of his obligations upon their maturity—viz., the difference in the contract price and the market value at the time and place of delivery subject to a reduction (of damage) by any circumstances of which the buyer ought reasonably to have availed himself or did avail himself to reduce or mitigate his loss. And it is no defense to the seller and no ground for a reduction in the buyer's damage that the latter contracted for the product for a purpose not mentioned in the contract, and that he had no use for it, or that he failed to go into the market and buy elsewhere.

That where the seller defaulted in making a periodic delivery under the contract a demand by the buyer that the seller perform his obligation does not amount to a waiver by the buyer of his right to sue for the entire breach upon the seller's refusing to comply with such demand.

In the instant case the seller contended he had a right to refuse further deliveries under the contract because the buyer had failed to make payment for a past delivery. Assuming that the seller could so justify his refusal to make further deliveries, yet, says the court, since the parties to a contract may in the course of its execution depart from its terms and pay or receive money under such departure without any right in the other party to treat such departure as a violation or breach of the contract, in the absence of reasonable notice of his intention to do so given by the other party, the seller cannot, after having acquiesced in such departure and having failed to give such notice to the buyer, justify his refusal to comply with his obligation to deliver under the terms of the contract upon the ground that the buyer has failed to make payment for a past delivery.

Further it was claimed there was a tender of the product by the seller to the buyer. The contract provided that delivery was to be made at such place as the buyer may direct. Where no place is agreed on, under

the statute sold goods must be carried to the person entitled to them, if residing within the state. There being nothing in the nature of the product or in the contract from which another place of delivery could be inferred in the absence of any direction from the buyer as to the place of delivery, to constitute a valid tender the product should have been carried to the buyer in person, but the carriage to his place of business, in his absence and without his knowledge, did not constitute a valid tender under the contract.

Judgment against the seller was affirmed.

When Mechanical Equipment Does and When It Does Not Become Fixtures

The manufacturers of chemical machinery are often confronted with the question of whether title to machinery sold by them and installed in plants may be retained, and whether attempts to retain are defeated by installing of the machinery. The question is a big one with many angles, and facts in any particular case might remove it from the operation of the rules as generally laid down.

Some propositions of the law involved came up in the recent decision in the action by the Atlantic Refining Co. against H. Flinberg to recover a tank, pump and equipment. Defendant claimed possession and title to the property, because after it was placed upon the land it became fixtures, and title passed when he purchased the real estate upon which the chattels had been placed by the company, the purchase of the real estate being made without notice that the seller had consented that the chattels should not become fixtures at the time of installation. Therefore, for lack of notice to him when he purchased the real estate, the equipment passed to him with the title to the real estate.

The company contended that defendant had notice or knowledge that the equipment was its property and therefore was not an innocent purchaser and for this reason it did not pass to defendant when he purchased the real estate.

The company brought its action in replevin. The court stated that the action of replevin lies for the possession of goods and chattels unlawfully detained from the owner or the person entitled to the possession thereof. The primary object of the action is the recovery of the property itself with damages for the taking and detention thereof. Secondly, the object is the recovery of a sum of money equivalent to the value of the property.

THE LAW OF FIXTURES

In this case defendant claimed the equipment involved constituted what is known in the law as fixtures. The court says a fixture has been defined as a thing which, though originally a movable chattel, is, by reason of its annexation to land, regarded as a part of the land, partaking of its character and belonging, in the ordinary case at least, to the person owning the land. The owner of a chattel and the owner of land may agree that the annexation of the chattel to the land shall not change the legal character of the chattel or affect its ownership, and such an agreement is generally regarded as valid between the parties. Where, however, the land passes into the ownership of a third person, not a party to such an agreement and without notice or knowledge thereof, the purchaser of the land is not bound by such an agreement, but is entitled to the thing annexed to the land, as forming a part of the land. If any sub-

stantial part of the complete equipment necessary for the use of the chattels in question was fastened or attached to the freehold in a permanent manner, then all is to be considered as so attached and also everything used in working it.

Notice or knowledge on the part of the purchaser of real estate relative to an agreement respecting the title to fixtures on the premises purchased being in some person other than the owner of the real estate would be actual notice or knowledge of the fact or such information of a reliable character with respect to the ownership as would impose upon him the duty of making inquiry as to the actual ownership of the fixtures upon the land.

In the instant case the court said that if the purchaser, defendant herein, did not have notice, and was an innocent purchaser for value, then the title to the chattels would pass to him with the title to the land, but if he had notice and knowledge of the fact that the fixtures in question belonged to somebody other than the person from whom he purchased the land, then he would not be an innocent purchaser for value, and as between the true owner and himself the true owner would be entitled to the possession of the property.

Any notice, or knowledge of any fact, that would put him upon inquiry as to the ownership of the property would place a duty upon him to inquire and ascertain, if possible, the true owner; and the question of this notice or knowledge is ordinarily one of fact to be determined by a jury, where such fact is in dispute.

The court decided that defendant herein had such a notice and that therefore the equipment was not a fixture passing with the title upon the sale of the land.

Synopsis of Recent Chemical & Metallurgical Literature

A Theory on the Gradual Hydrolysis of Certain Salts.—The hydrolysis of salts being an ionic phenomenon, it would follow that such a reaction ought to be extremely rapid in all cases; but experience has proved that there are salt solutions whose hydrolysis is slow and may still continue even after many months. It has been found that all the salt solutions presenting this anomaly contain some of the acid or base in colloidal suspension; it would seem, therefore, that there is a relation of cause and effect between the presence of a colloid and the slow hydrolysis. A theory underlying this fact has been advanced by A. TIAN in a note presented before the French Academy of Sciences (*Comptes rendus*, May 9, 1921, pp. 1179-1181). He states that the extremely fine particles of the colloid unite to form grains of increasing sizes, which for a given mass present gradually decreasing surfaces, and that the hydrolysis of a salt is limited by two reactions, both of which reproduce the salt and the water with the acid or base freed during hydrolysis. The first reaction would take place in the aqueous phase between ions, this being exactly the reverse of hydrolysis. The second reaction, which he calls "supplementary retrogradation," takes place between the insoluble and liquid phases by the action of the other soluble element of the salt. The velocity of this reaction diminishes when the space between the two phases decreases and it follows that the hydrolysis slows down with the evolution of the colloidal solution. To prove this theory he has established experimentally that:

Slow hydrolysis is a function of the polymerization of the colloid and that there is effectively a regeneration of the salt by a reaction in which the colloid takes part. In the

first case he has utilized the very interesting properties of gels which hinder the displacement of colloidal particles, and by using gelose, animal gelatine or silica to produce a solidified state he stopped the hydrolysis. In the second case he was able to vary the rate of the hydrolysis by varying the amount of the colloid.

Electrochemical Industries.—The June, 1921, issue of *General Electric Review* contains an article by JOHN A. SEEDE in which there is an interesting summary of developments in the electrochemical industries. Electrothermic applications such as those used for smelting, melting and refining of various metals and alloys are of increasing importance. The first electric furnaces for melting and refining steel when introduced about 1904 were generally regarded as laboratory curiosities. Today we have furnaces with three electrodes normally rated at 40 tons holding capacity and capable of pouring 65 tons. During this period brass-melting furnaces have been developed and their adoption has far outstripped that of steel furnaces.

The author classifies the products of the principal electrochemical industries into electrothermic and electrolytic products. The electrothermic products are alundum, calcium carbide, calcium cyanamide, carbon bisulphide, ferro-alloys, graphite, iron, nitrates and nitrites, phosphorus and barium oxide. The electrolytic products include aluminum, caustic soda and potash, electrolytic iron, lead, magnesium, chlorine, chlorates and perchlorates, hydrogen and oxygen.

The following table lists these products with the approximate energy consumption required for their production. The author assumes the power to be furnished at \$20 per horsepower-year and from this he derives the percentage of the market price represented by the cost of power. This power cost, which is obviously obtainable in but a few localities, is used throughout the calculations in order to obtain comparable data.

ELECTROCHEMICAL PRODUCTION COST OF VARIOUS MATERIALS

Material	Kw.-Hr. per Ton	Present Market Price of Product	Cost of Power per Ton	Per Cent Cost of Power to Market Price
Aluminum.....	30,000	\$570	\$90.00	15.80
Alundum.....	2,000	60	6.00	10.00
Barium oxide.....	1,200	*	3.60	*
Cadmium.....	2,500	2,200	7.50	3.40
Calcium carbide.....	4,000	80	12.00	15.00
Calcium cyanamide.....	3,750	300	11.25	3.75
Carbon bisulphide.....	850	160	2.55	1.60
Carborundum.....	8,500	*	25.50	*
Caustic soda 2 000 lb. Chlorine, 1,760 lb. }	3,000	{ 72 } 220	90.00	30.80
Copper (electr ly ic ref.).....	300	240	.90	0.38
Copper (electroly ic).....	2,600	240	7.80	3.25
Ferrocromium (60%).....	8,000	180	24.00	13.30
Ferromanganese (76%).....	5,000	90	15.00	16.6
Ferromolybdenum (60%).....	8,400	3,000	25.20	0.84
Ferrosilicon (50%).....	5,000	80	18.00	22.50
Ferrosilicon (75%).....	10,000	135	30.00	22.20
Ferrotungsten (70%).....	7,600	700	22.80	3.25
Ferro-uranium (40%).....	8,600	4,800	24.00	0.50
Ferrovandium (35%).....	6,800	3,500	20.40	0.58
Graphite.....	7,800	200	23.40	11.70

* Figures not available.

In like manner the second table compares the electrothermic melting and refining of a number of metals and alloys. The power cost is figured at 2c. per kw.-hr. throughout, and the percentages are, therefore, probably somewhat more in accord with actual practice.

ELECTROTHERMIC MELTING AND REFINING OF METALS

Material	Kw.-Hr. per Ton	Market Price per Ton		Power Cost at 2c.	Per Cent Cost of Product
		Raw Materials	Product		
Aluminum.....	500	\$570	\$1,200	\$10.00	0.80

Recent Chemical & Metallurgical Patents

British Patents

For complete specifications of any British patent apply to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Monoazo Dyes.—Monoazo dyes are obtained by coupling *o*-diazophenols, *o*-diazonaphthols, or their nitro, sulphonic, or carboxylic derivatives, with 4:6-diamino-1:3-xylene. According to examples, the diazo compound of picramic acid, and the diazo compound of 5-nitro-2-aminophenol, prepared by diazotizing 2:4-dinitraniline in sulphuric acid solution and pouring the product into ice-cold sodium carbonate solution, are employed; the resulting dyes give orange-brown and brown shades on wool with chrome mordants. (Br. Pat. 160,848; G. T. MORGAN, Birmingham, and BRITISH DYE-STUFFS CORP., LTD., London. May 19, 1921.)

Artificial Silk.—Artificial silk threads obtained by squirting a solution of cellulose acetate or other cellulose ester in a volatile solvent are prepared in a completely finished condition by passing the threads on leaving the squirting nozzle through gases or vapors such as sulphur dioxide, carbon dioxide or air which may be heated, or through an exhausted chamber, and then leading them directly to the winding or spooling apparatus. As shown, the parts of the apparatus are inclosed in a casing 1; in the top of the chamber is the combined squirting nozzle 6 and filter 5, arranged to swing outward, and the threads pass through a tube 8, then through a guide 13 traversed by the winding mechanism, or to a reel or spool 10 located in the lower part of the casing, mounted on a pivoted carrier 17, and driven by a belt 11, from a shaft 12; access to the reel is obtained by a door 16. In the lower part of the casing is an electric lamp 15 which causes a current of hot air to pass up the tube 8; and this tube may be warmed by a coil. The squirting nozzles may be located in the lower part of the casing, or the threads may be projected in a horizontal direction; and the threads may be stretched or twisted before reeling. (Br. Pat. 160,859; G. F. J. BOUFFE, Derby. May 19, 1921.)

Gas Analysis Apparatus.—An apparatus for analyzing gases comprises a receptacle *a* containing an absorbent for the constituent to be determined, the ends of the vessel being closed by diaphragms *e*, *e'*, the first connected to a pressure-indicating device and the other diaphragm designed to be adjusted in position as by a screw *h* and nut *i* so as to control the inlet and exit of gas through a valve *n*. In use, a negative pressure is produced in the vessel by distending the diaphragm *e'*, until the pointer makes a complete revolution; the valve *n* is then momentarily opened to admit a sample of gas; the final pressure shows the proportion of the sample absorbed by the reagent; the

valve *n* is then opened and the diaphragm *e'* pressed inward to discharge the residual gas. (Br. Pat. 160,930; R. H. DAVIS and C. ROSLING, both of Westminster. May 25, 1921.)

Distilling Ammonia.—In stills for treating ammoniacal liquor to separate ammonia, which is used to form ammonium sulphate, in which the liquor passes down a primary still for separation of sulphuretted hydrogen and carbon dioxide, then into a liming chamber, and through a final still, a portion of the vapor is withdrawn from the liming chamber and passed through a reflux condenser to separate water, and into an ordinary condenser to obtain a concentrated solution of ammonia, which may be used to neutralize free acid in ammonium sulphate. (Br. Pat. 161,244; R. P. DOUGLAS, Bolton. May 25, 1921.)

Magnesium Chloride.—Oxygen compounds of magnesium are converted in the presence of sulphur or its non-oxygenated derivatives—e.g., sulphur chloride—into anhydrous magnesium chloride by the action of a chlorine containing gas. Preferably magnesia is used as the starting material, but the carbonate and sulphate of magnesium and the double carbonate or silicate of calcium and magnesium may also be employed. The reacting materials must be dry and substances capable of forming water must be absent. Until the last stage is reached the process is carried out below 700 deg. C. so that the product does not fuse and thereby impede the reaction. A little carbon is added when the chlorination is conducted at about 300 deg. C. to convert the small quantity of magnesium sulphate which is also produced, into magnesia. The latter is readily separated from the fusible chloride. Any apparatus for treating solids with gases may be used—e.g., the raw materials may be fed into the top of a cylindrical vessel and chlorine passed in at the bottom; the sulphur chloride and other condensable products being cooled and returned to the reaction-zone. Advantageously the process may be worked in conjunction with the electrolysis of the magnesium chloride, the hot chlorine from the latter being used direct for the chlorination. (Br. Pat. 161,165; not yet accepted; V. M. GOLDSCHMIDT, Christiania. May 25, 1921.)

Hardening Tools.—In hardening tools the tool is heated and hammered to form a skin or casing, again heated and placed in a mixture of potassium ferrocyanide and bone ash, whereupon the container is placed in a furnace and heated to bright redness. After a short time a further quantity of the powered mixture may be added. The tools are finally quenched in water, and large tools may be clamped between metal plates during cooling. (Br. Pat. 161,446; W. TATE, South Hylton, near Sunderland. June 1, 1921.)

Heat-Treatment of Copper Alloys.—Relates to the heat-treatment of copper alloys and consists in subjecting alloys of copper, manganese and other metals such as aluminum, zinc, tin or silicon, after they have been cast, rolled or forged, to a prolonged heating at a temperature below red heat. In an example an alloy consisting of 10-15 per cent manganese, 10-15 per cent aluminum, the remainder being copper, which when rolled, annealed and cooled has a tensile strength of 66 kg. per sq.mm. and an extension of 21 per cent, after being subjected to a temperature of 220 deg. C. for twenty hours, showed a tensile strength of 96 kg. per sq.mm. and an extension of 0 per cent. The hardening is stated to render the metal suitable for the manufacture of knives. A marked hardening effect takes place in the case of brass alloys containing a high proportion of manganese. Such an alloy containing 51 per cent copper, 40 per cent zinc and 9 per cent manganese after rolling at a high temperature, forging and annealing at 600 deg. C. and cooling shows a tensile strength of 54 kg. per sq.mm., extension 11 per cent and a Brinell hardness of 166. After heating for thirty-six hours at 230 deg. C., the same alloy shows a tensile strength of 60 kg. per sq.mm., extension 2 per cent and a Brinell hardness of 260. Manganese, silicon and copper alloys hardened by this method at temperatures of 200 to 400 deg. C. may be used in place of tin alloys for bearing liners. Other examples are given in the specification. (Br. Pat. 161,537; not yet accepted; ISABELLEN HÜTTE GES., Dillenburg, Hessen-Nassau. June 1, 1921.)

Motion to Fix Standard of Comparison in M. S. Ltd., vs. Butte & Superior Co. Accounting Proceedings

On June 21 a motion of unusual nature was argued in this case before Judge Bourquin, U. S. District Court, sitting at Helena, Mont. By this motion, Minerals Separation, Ltd., seeks to have the court instruct the master, L. P. Donovan, who has recently been appointed in the Butte & Superior accounting, as to what shall constitute the standard of comparison for determining the amount of profits for which Butte & Superior company may be held liable as a result of the adjudged infringements.

In the case before the Supreme Court, Minerals Separation was not upheld in its contention that the process which Butte & Superior company had used (with oil in an amount in excess of 1 per cent upon the ore) was an infringement. Minerals Separation then claimed that petroleum was not "a frothing oil" upon defendant's ore, but the Supreme Court said that the patent made no disclosure as to "frothing oils" and held the plus 1 per cent process not to be infringing. Butte & Superior company took this plus 1 per cent process as a standard of comparison.

This motion, just argued, had as its announced object the prevention of extending the accounting proceedings beyond proper limits. Defendant sees in the motion an attempt to restrict it to water concentration as the sole standard of comparison.

Reference was made by plaintiff's counsel to the Miami accounting as being unduly prolonged, but it was explained by defendant's counsel that the Miami accounting—except for a brief period—had not been, thus far, an accounting at all, but that the time consumed had been almost entirely devoted to the examination of about eleven subsequent practices, in the use of which by the Miami company infringement was claimed by Minerals Separation.

Counsel for defendant, in argument, summarizes the contentions of the parties as follows:

The plaintiff sets forth in its hearing papers:

(1) That under the law, the only proper standard of comparison is a process or processes known and available at the date of the issuance of the patent in suit which would have given the best results with the defendant's ore if used by the defendant; and that in any event the standard of comparison must be a process or processes known and available prior to the commencement of infringement by the defendant.

* * * * *

(4) That for the infringing acts of the defendant during the few days in January, 1917, after January 9, 1917, and the greater part of February, 1917, during which defendant infringed the patent in suit, the proper standard of comparison is water concentration.

(5) That for the infringing acts of defendant from some time in May, 1917, to and including June 5, 1919, the proper standard of comparison is water concentration.

The defendant in its answer says:

(1) The statement of law contained in the first paragraph of plaintiff's motion is neither accurate nor complete. Anything free and open to be used at the time of infringement is a proper standard of comparison, and defendant has the right, if it desires, not only to set up alternate standards of comparison but to introduce evidence going to the question of reasonable or established royalty, so that the court, after hearing the evidence submitted, may determine what measure of damages or profits best fits the facts of the case and is most just.

* * * * *

(3) Defendant admits that all those forms of water concentration which were free and open to be used

during the infringing period are available standards of comparison, but it denies that they are the only proper standards of comparison.

(4) Defendant further says that there are several standards of comparison available in this case, one of which has already been presented provisionally by defendant in its statement of account and another of which is the electrolytic process, and defendant asserts that it has the right to introduce evidence as to each and every available standard of comparison upon which it desires to rely, as well as evidence looking to the question of determining a reasonable or established royalty, and all other evidence germane to the issues.

(5) Defendant further says that there is no evidence in the case as to what is the best standard of comparison, and that the present motion is an attempt to have the court rule on the admissibility of evidence, before it has been tendered by the defendant. Defendant avers that the questions arising on this accounting in this connection are complicated and cannot be justly determined until all the evidence is in and a complete case made out.

Plaintiff's counsel asked the court to instruct the master on the law, to the effect that the standard of comparison must be a process known at the date of the invention. Defendant contended that the proper rule was that the standard must be known at the date of the infringement.

Counsel for defense further stated that there was record of only one instance in which the court had given preliminary instructions at this stage of the accounting, and that these instructions had been of a very general character, not at all like those asked for here; and further that the instructions were so modified by the accompanying explanation as to quite relieve the master, to whom they are addressed, from being in any way hampered.

Both parties are preparing briefs upon submission of which decision will shortly be rendered.

Stanley Patent Bill Goes Over in Senate for Further Consideration

So that a further report may be submitted by the Secretary of War, the Stanley patent bill, providing that foreigners shall manufacture within two years any article they patent in this country, has been allowed by the Senate to go over for further consideration. Frederick P. Fish of Boston, a patent attorney of national reputation, takes the position that the legislation would set up a bad policy and establish a dangerous precedent. In view of the objections from such an authority, Senator Stanley expressed his willingness to wait until the Secretary of War could have opportunity to reply to Mr. Fish's arguments.

Senator Stanley declared, however, that he is thoroughly convinced of the necessity of the legislation. He thinks the only effect it can have is to protect the Ordnance Department in a great number of patents that have been perfected by American engineers upon American ordnance. These same inventions, Senator Stanley says, which the Americans used during the war and are now using but which they did not patent, have been patented by foreigners and sold to the Krupps or other foreign concerns, with the result that we cannot use our own patents for our own defense. Senator Stanley also pointed out that the United States is the only country in the world that has no such legislation.

In the course of his remarks, Senator Stanley said that he is strongly of the opinion that the junking of patents should be prevented. He declared that this is one of the most fecund sources of corruption and of monopoly. He called attention, however, to the fact that nothing of that kind was attempted in this bill.

Fall Meeting, Cellulose Section, A.C.S.

The president and secretary of the American Chemical Society have authorized another meeting of the Cellulose Section in connection with the fall meeting of the parent society in New York, Sept. 6 to 10, 1921. Prof. Harold Hibbert has been reappointed chairman and Gustavus J. Esselen, Jr., secretary. This will be the fourth consecutive session devoted to cellulose and its derivatives, a symposium on the subjects having been held in both St. Louis and Chicago and the first meeting of the Cellulose Section, as such, at Rochester last April. At this last meeting great interest was shown and there is no doubt that the Cellulose Section has made a place for itself in the activities of the American Chemical Society.

It is the plan this year to issue the preliminary program much earlier than on previous occasions, and accordingly those who plan to present papers before the Cellulose Section are urged to send the titles at once to G. J. Esselen, Jr., secretary of the section, 248 Boylston St., Boston, 17, Mass.

Program of the Summer Meeting of the American Ceramic Society

The midsummer meeting of the American Ceramic Society will be held at Canton, Alliance, Sebring and East Liverpool, Ohio, July 25, 26 and 27, inclusive, with headquarters at the Hotel Courtland, Canton, Ohio. The advance program for trips at this meeting is as follows:

MONDAY, JULY 25

10 a.m.—Leave Hotel Courtland on special cars for the Dueber Watch Case Manufacturing Co.

12 Noon.—Return to hotel for luncheon.

1:30 p.m.—Take special cars for the Bonnot Co., manufacturer of clay machinery.

3 p.m.—Visit the Canton Stamping & Enameling Co. or the Republic Stamping & Enameling Co. Due to the limited time available, it will be impossible for members to visit both enameling plants, therefore this portion of the trip will be left open to individual choice.

5 p.m.—Return to hotel.

7 p.m.—Leave Hotel Courtland in automobiles for Congress Lake.

7:30 p.m.—Banquet Congress Lake Country Club.

The drive from Canton to Congress Lake is a very fine one over about eighteen miles of perfect brick pavement. The country club is one of the best in the country and the cool, refreshing breezes from the lake, combined with a delicious and appetizing menu and exquisite service, make this an ideal place to dine during a hot July evening.

Besides a few short after-dinner speeches by speakers of national reputation, there will be several unique entertainment features.

TUESDAY, JULY 26, AT ALLIANCE AND SEBRING

9 a.m.—Leave on special cars of the Stark Electric for Alliance, arriving at 10:10 at Mahoning Ave., where the party will be met with automobiles and taken direct to the No. 2 plant of the Alliance Brick Co. Here the members will have the opportunity to see one of the most modern equipped brick plants in the country, the bricks being burned in a Richardson compartment kiln with producer gas.

1 p.m.—A complimentary luncheon will be given at the Alliance Country Club by the ceramic industries of Sebring.

2 p.m.—Party will leave by automobile for Sebring, where the Limoges China Co., the Sebring Pottery Co. and the Strong Enamel Co. will be visited. The Dressler tunnel kilns at the Limoges China Co. and the McFall oil-burning equipment at the Sebring Pottery Co. will be of special interest to members.

5:45 p.m.—Return to Canton on special cars of the Stark Electric.

9 p.m.—Theatre party, Myers Lake.

10:30 p.m.—Complimentary smoker, Myers Lake.

WEDNESDAY, JULY 27, AT EAST LIVERPOOL

7 a.m.—Leave Hotel Courtland for East Liverpool in automobiles, arriving at about 10 a.m. Visit R. Thomas & Sons Co., high-voltage electrical porcelain factory, oil-burning kilns, tunnel drier.

11:45 a.m.—Complimentary luncheon at Elks Club.

12:45 p.m.—Visit Homer Laughlin China Co., Newell, W. Va., and Knowles, Taylor & Knowles Co., East Liverpool, Ohio, both general ware plants. The visit to the factories in East Liverpool will be concluded in ample time for members to take the 5:40 train to Rochester, Pittsburgh and the East. At Rochester, connections can be made with Pennsylvania train 115 for Chicago and the West.

ENTERTAINMENT FOR LADIES

Special plans for the entertainment of the ladies have been made by the committee. In addition to the visit to the Dueber Watch Works on Monday morning, the banquet on Monday evening, the complimentary luncheons on Tuesday and Wednesday and the theatre party on Tuesday evening to which the ladies are cordially invited, there will be automobile trips on Monday afternoon, Tuesday and Wednesday to places of interest.

AUTOMOBILE TRIP CANTON TO EAST LIVERPOOL

The automobile trip from Canton to East Liverpool is of special interest, as it is a drive over nicely paved roads and through beautiful country. All members within a radius of 200 miles of Canton are urged to bring machines in order that members from a distance may enjoy this most delightful trip.

Fellowships in Metallurgy at University of Missouri

In co-operation with the United States Bureau of Mines and the State Mining Experiment Station, the School of Mines and Metallurgy of the University of Missouri offers four fellowships. These fellowships are open to graduates who have the equivalent of a Bachelor of Science degree and have had the proper training in mining, metallurgy or chemistry, and who are qualified to undertake research work. The income of each fellowship is \$800 per annum for the twelve months beginning July 1, 1921.

Fellows will register as students in the School of Mines and Metallurgy of the University of Missouri and become candidates for the degree of Master of Science in Mining or Metallurgy (unless this or an equivalent degree has been earned). Their class work will be directed by the heads of the departments of instruction, but the greater portion of their time will be spent in research work under the direction of the Bureau of Mines staff resident at the School of Mines. The purpose of this work is to undertake the solution of definite problems confronting the mining and metallurgical industries of the State of Missouri. For 1921-22 the four fellowships will be granted in the following subjects: Mining; ore dressing; physical metallurgy (heat-treatment of steel); electrometallurgy (zinc).

Applications, with a certified copy of collegiate record, statement of professional experience, and names and addresses of three references, will be received up to Sept. 1, 1921, by the Director, School of Mines and Metallurgy, University of Missouri, Rolla, Mo.

List of Research Chemicals in Preparation

Research chemicals and others not commonly available are to be listed in a forthcoming publication of the National Research Council. Dr. C. J. West, secretary of the committee, is sending out requests to every manufacturer of chemicals, stains, drugs and similar commodities asking them to furnish him with the list of products actually manufactured or products for which American companies are agents. This work will not include a listing of heavy chemicals or the more common chemical reagents, but it is intended to assist those doing research or occasionally using rare chemicals as raw materials to get in touch with all manufacturers of these products.

Special emphasis is being made by this committee on the importance of small orders. Where a company is willing to handle these, say in quantities less than 1 lb., this distinction will be indicated in the printed list.

Any manufacturers who have not already been reached by the committee should communicate with Dr. C. J. West, Committee on Research Chemicals, National Research Council, 1701 Massachusetts Ave., Washington, D. C.

Industrial Research Laboratories

Research facilities and the development activities of American industries are to be described in the forthcoming revision of bulletin of the National Research Council, No. 2, "Research Laboratories in Industrial Establishments of the United States of America." Only 300 such laboratories were listed in the first edition, but it is hoped that several hundred new names will appear in the revision and that a more nearly complete reference list will thus become available. The general demand for the first edition of the bulletin shows the wide interest in this subject and the importance of having every laboratory which devotes even a portion of its time to research properly listed.

The Council requests information from directors of research who have not already supplied it. The following data are wanted: Name and address of firm and address of laboratory; name of director of research; number on laboratory staff (classified as chemists, engineers, bacteriologists, etc.); approximate proportion of time spent on research; chief lines of research; unusual features of equipment; research laboratory space; date of organization of research laboratory and annual expenditure for research. Confidential information is not desired.

It is also requested that librarians in the service of the industries bring this notice to the attention of the proper officials in their organizations.

This material should be furnished as promptly as possible to the Research Information Service, National Research Council, 1701 Massachusetts Ave., Washington, D. C.

Dupont Fibersilk Co. Plant in Operation

Manufacture of artificial silk has been begun at the new plant of the DuPont Fibersilk Co. located on the Niagara River at Buffalo, N. Y. Operations are proceeding in a very satisfactory way and at the present time the plant is producing 1,000 lb. per day of 150 denier, which is one of the most widely used sizes of thread, but both the finer and coarser counts will be made in accordance with the demands of the trade. The product has already been tried out in several of the manufacturing industries using this size, such as those producing hosiery, fancy knitting, sweaters, neckties, broad silk weaving and others. The output of the plant will be increased from now on up to capacity, which will be in the neighborhood of 1,500,000 lb. of artificial silk per year. All of the product will be sold in the form of skeins and will go direct to manufacturers. When in full operation, the plant will employ approximately 600 operatives, about half of whom will be women.

The DuPont Fibersilk Co., which is a subsidiary of E. I. du Pont de Nemours & Co., owns 100 acres of ground on the Niagara River between Buffalo and Tonawanda and has installed its own facilities, including water supply, sewerage, etc. The DuPont Engineering Co. of Wilmington, Del., is the architect, engineer and designer for the plant and construction work was started in August, 1920. The buildings cover a total area of approximately 200,000 sq.ft. and are mostly one story in height. The main buildings are of brick, monitor type roof, glass sides and high head room, insuring ample light and proper ventilation. These main buildings are arranged so that the various processes of manufacture follow each other in proper sequence, thus insuring a minimum of handling. The balance of the buildings are concrete. The entire plant has been equipped with sprinkler system.

Power is supplied from a plant of 1,500 hp. which has been erected on the property and in addition to this, arrangements have been made to obtain electric power from one of the nearby electric power plants.

Special attention has been given to the comfort and convenience of employees and a modern cafeteria and girls' rest rooms have been provided. There are also medical and dental offices. Every effort has been made to insure the best of working and living conditions.

The DuPont Fibersilk Co. was incorporated in April, 1920, as a result of an agreement with the Comptoir des Textiles Artificiels of Paris, France. The latter company controls many of the large silk plants of Europe and has

been producing artificial silk for many years. The DuPont Co. has done extensive experimental work during the past six years and has developed a fund of knowledge and experience which will help to make the product of the finest possible grade.

The officers of the DuPont Fibersilk Co. are L. A. Yerkes, president; B. M. May, treasurer; M. du Pont Lee, production manager; George Rocker, chemical director; E. K. Gladding, plant superintendent; C. J. Bacon, chief engineer.

The executive and sales offices of this company are located at Buffalo.

Insecticide and Disinfectant Manufacturers' Association, Atlantic City Meeting

The seventh mid-summer meeting of the Insecticide and Disinfectant Manufacturers' Association was held at Hotel Traymore, Atlantic City, June 13 and 14. President H. W. Cole of The Barrett Co. presided, and the special guests of the occasion were Dr. J. K. Haywood, chairman of the Insecticide and Fungicide Board, U. S. Department of Agriculture; Prof. Thomas J. Hedlee, Entomologist, State of New Jersey; and William D. Hartley, representative of McDougall Bros., Ltd., Manchester, England.

The address of welcome was given by A. L. Bobrick, president of the Sanitary Products Corporation of New York, chairman of the committee on publicity and program, and the response was by A. S. Hickerson, vice-president of the Worrell Manufacturing Co. of St. Louis.

The president's address, which opened the business of the meeting, reviewed the progress of the association during the past six months, especially in committees, and he expressed the appreciation of officers and committee chairmen for the hearty co-operation of the membership at large.

W. H. Gesell, of the Lehn & Fink Co., Inc., reported for the committee on disinfectants, which was followed by the report of the committee on insecticides, prepared by the committee chairman, R. N. Chipman, president of the Chipman Chemical Engineering Co. of New York, and read by C. L. Weirich, chief chemist. Mr. Bobrick submitted the report for his committee on publicity and program, after which Dr. William Dreyfus, chief chemist of the West Disinfecting Co., as chairman of the committee on standardization of disinfectants, reported for his committee and this report as submitted and accepted included the recommendation by the committee on the adoption of the Hygienic Laboratory method of testing disinfectants as received from Dr. G. W. McCoy and about to be published by the Hygienic Laboratory of U. S. Public Health Service.

Following luncheon Prof. Hedlee gave a most interesting talk upon his work as State Entomologist and set forth the possibilities his field presented to the trade.

Mr. Hartley then addressed the association informally in regard to trade conditions in England, especially with respect to exportations. When questioned as to the effect of the coal strike upon market values of creosotes, cresylics, etc., Mr. Hartley expressed the opinion that such supplies of coal had been furnished to the essential industries, including the gas and coal oven plants, and that an advance in prices of these products was not expected.

The reports of the officers and committees, combined with the interesting addresses given by the guests of the occasion, contributed to make the meeting a most successful one, and those in attendance were deeply impressed with the work the association was doing and its future prospects.

Standards Recently Approved by the A. E. S. C.

Standards recently approved by the American Engineering Standards Committee include four copper specifications submitted by the American Society for Testing Materials as "Tentative American Standard," as follows:

- 9—1921—Soft or annealed copper wire.
- 10—1921—Lake copper wire, bars, cakes, slabs, billets, ingots, and ingot bars.
- 11—1921—Electrolytic copper wire bars, cakes, slabs, billets, ingots and ingot bars.
- 12—1921—Battery assay of copper.

Exports and Imports of Chemicals

A further decrease in imports of chemicals occurred during May. The total value of imports during that month was \$6,568,761. This is half the monthly average throughout the year preceding. The decrease is very marked when compared with imports in May, 1920, when their value aggregated \$21,021,162. A decrease also is shown over April of 1921, when the value of imports totaled \$7,416,478. The figures are those of the Bureau of Foreign and Domestic Commerce.

Colors and dyes formed the only item on the entire list of May's imports which showed an increase over the imports of May a year ago. Colors and dyes to the value of \$307,735 were imported during May of this year, whereas the value of imports during May of 1920 was \$263,281. Imports of coal-tar products, as a whole, decreased from \$634,840 to \$401,837. There was a decided slump in the gums imported. Imports in May of 1920 were valued at \$5,714,192. In May of 1921 imports of gums were valued at \$1,259,209. Outside the main groups, some of the chemicals imported during May, compared with the figures for the corresponding month of 1920, are as follows:

	May, 1920	May, 1921
Ammonia, muriate of.....	\$79,077	\$21,350
Glycerine	343,494	7,931
Lime, citrate of	761,277	676
Potash, nitrate of.....	122,748	15,341
Soda, cyanide of.....	41,935	12,392

Exports of chemicals were in small volume during May. The value of all chemicals exported during that month was \$4,366,119. This compares with \$4,525,852 in April, 1921, and with \$18,030,514 in May of 1920. The decrease was general, as compared with exports in May of last year. Exports of acids declined from \$840,282 to \$97,983. Dyes and dyestuffs to the value of \$3,437,885 were exported in May, 1920. In May of this year the value of exports was \$396,524. Extracts for tanning declined from \$260,118 to \$75,277. In May of 1920 the exports of sodas were valued at \$2,715,673. In May of this year the value of the soda exports was \$435,037.

There was one item on the list which showed a very decided increase. In May of this year, 18,102,679 lb. of benzene was exported from the United States. This compares with exports of 1,483,096 lb. in May of 1920. Exports of certain chemicals which move in smaller volume are shown in the following comparative table:

	May, 1920	May, 1921
Copper, sulphate of.....	\$38,619	\$7,851
Formaldehyde	230,053	33,937
Glycerine	29,406	11,357

Chemists Exonerate Pyrites Plant from Fume Damage

M. R. Lamkey, plant physiologist, and Thomas F. Mains, plant pathologist, State Agricultural Experiment Station, Newark, Del., have tendered a formal report to the City Council, Wilmington, following an inspection of property at South Wilmington, held to have been damaged by fumes from the plant of the Pyrites Co., Ltd., in this section. The report sets forth that there is no absolute evidence that the damage was done by fumes or smoke from this plant, and while without any positive conclusion, it is attributed to severe frosts in the early spring. Referring to the fact that a month had elapsed before the investigation was made, due to neglect in calling on the station chemists, the report says: "We wish to emphasize the fact that many natural conditions can produce injuries so nearly similar to fumes or smoke injury that no investigation, no matter how expert, can distinguish the two after an exposure of several days to weather conditions. The injuries must be seen as they are produced, and the conditions under which they are produced must be known before a conclusive statement can be made."

New Stack at Midvale, Utah, Smelting Plant

The United States Smelting, Refining & Mining Co. has begun the construction of a new stack at its smelting plant at Midvale, Utah, to be 450 ft. in height and estimated to cost about \$150,000.

Personal

PERCY E. BARBOUR, assistant secretary of the American Institute of Mining and Metallurgical Engineers, who has been seriously ill for some time past, is improving in health and expects to resume his duties before the end of July.

H. O. CHUTE, chemical engineer, of New York, is now associated with the Cannon-Swenson Co., Chicago, for work in wood distillation.

C. E. DAVIES has been appointed managing editor of *Mechanical Engineering*, the publication of the American Society of Mechanical Engineers, to succeed the late L. C. French.

Dr. LIVINGSTON FARRAND of the American Red Cross, Washington, D. C., has been elected president of Cornell University, Ithaca, N. Y.

ALEX. L. FEILD, who has been engaged in metallurgical investigations at the plant of the Electro Metallurgical Co., Niagara Falls, N. Y., has been recently transferred to the new research laboratory of the Union Carbide & Carbon Corporation, Thompson and Nelson Aves., Long Island City, N. Y. Mr. Feild was at one time assistant metallurgist in the U. S. Bureau of Mines, Pittsburgh, Pa., and later was research physical chemist with the National Carbon Co., Inc., Cleveland, Ohio.

H. O. HOFMAN, professor of metallurgy in the Massachusetts Institute of Technology, has been made an honorary member of the American Institute of Mining and Metallurgical Engineers.

A. G. MACGREGOR has returned from his inspection trip to the new Cerro de Pasco smelter in Peru. The plant will be ready to operate before next summer.

W. W. MURRAY, until recently manager at the plant of the Continental Can Co., Cannonburg, W. Va., has become connected with the staff of the same company at Chicago, Ill.

EMIL POHL, Hartford City, Ind., an expert in the manufacture of grease-proof glassine paper and for the past fifteen years superintendent of the super-calender department at the Hartford City Paper Mills, has resigned. He will occupy a similar position at a paper mill in Wisconsin.

CHARLES F. RAND, a director of the American Institute of Mining and Metallurgical Engineers, has been made an honorary member of the Iron and Steel Institute (London).

FRED F. SHARPLESS has been elected secretary of the American Institute of Mining and Metallurgical Engineers to succeed Bradley Stoughton, resigned.

L. B. SKINNER has recently severed his connection as chief of the research staff of the Mid-West Refining Co. to carry on a general consulting practice in Denver, Col.

Dr. E. R. WOLCOTT, of the Western Precipitation Co., Los Angeles, is on an extended Eastern trip on matters concerning electric precipitation.

Book Reviews

TREATISE ON GENERAL AND INDUSTRIAL ORGANIC CHEMISTRY. By Dr. Ettore Molinari. 456 pp. Philadelphia: P. Blakiston's Son & Co. Price \$8 net.

The new edition of the Treatise on Industrial Chemistry should perhaps be more properly termed a treatise on organic chemistry in which the various compounds mentioned are selected with a view to their industrial application. The author points out the fallacies of other writers who deem that it is unnecessary for the student to be made familiar with the practical phase of the subject, claiming that a knowledge of theory is all that is required.

This conception in past years has been taken too literally, for today, when industry has attained an adult stage, the

author is justified in claiming that the time of the young technician cannot be wasted in a protracted and often sterile consideration of the theories involved.

In order to produce rapidly and with increased certainty a sound, practical man it is necessary to have a good theorist and to acquaint him with both a theoretical and practical study of the most salient industrial problems. In this book the author has endeavored to show the application of a great many organic compounds and has purposely left out of consideration a study of the industries themselves, thus making the book a reference volume on practical organic compounds, but at the same time he has pointed out possibilities for their further application and opportunities for the theorist as well as the technician to benefit from the matter therein contained.

This volume is an improvement on the former editions, and it is felt that the author should be congratulated upon the reception which the book has received. It is also felt that the book will be of great service to both manufacturers and chemists as an authoritative compilation of the important chemical compounds, presented in a comprehensive and readable manner.

ALLEN ROGERS.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, July 1, 1921.

There were no pronounced marks of interest shown in the chemical line during the past week. Only at intervals was there any positive character to trading and when prices moved, they did so in a perfunctory way. Changes were apt to be wholly fractional and the movement was as often a decline as an advance. The continued inactivity led to opinions that the market has gone as far as it can easily go in one direction, while others asserted that the absence of big buying orders was a result of the vacation spirit in the current holidays. It must be admitted that prices which rise under consumptive buying usually falter when orders of the sort are no longer obtainable. Not only are these particular orders absent when large buyers pursue this policy but traders and dealers who follow such a lead stop their own activities. These are possibly trivial considerations in a discussion of the chemical situation, but it is on such considerations that the present market is built up. In general, the market gave no clue as to what is coming next.

There are many buying interests that express the opinion that soda ash prices should be revised downward. These ideas can be traced directly to the fact that English and French ash has been offered through dealers at prices below those named by American producers. It is understood that these latter interests have not seen their way clear to quote lower on account of the relatively high overhead, freight and labor costs. The trade does not expect much change in caustic soda. The contract price is well sustained by producers and the supply of resale standard stock has been materially reduced in second hands where spot requirements are handled. The bichromates have not changed to any noticeable degree. Bichromate of soda varied about a half cent on spot during dull periods, but was not offered freely and the market was sensitive to small buying operations. Heavy importations of caustic, chlorate and carbonate of potash from Germany had a tendency to ease prices of these chemicals. Nitrite of soda was not active enough to permit a real test of values. Offerings of imported oxalic acid made a slight dent in the late advance in prices, although the tone was steady throughout the week.

FOREIGN INQUIRIES

Foreign inquiries have been noted from Italy, South America and other important points. Canada has bought quite moderately, but the inquiries seemed to be from those who were trying to feel the market. Prominent authorities who have just returned from South American ports admit

that surplus stocks of chemicals are slowly but steadily decreasing. The establishment of a foreign credit system would give the necessary punch to export business and several large interests are confident that ways and means will be found to stimulate foreign commerce.

It seems to be the consensus among men occupying high places in business and finance in outside quarters that the tide is gradually turning for the better. It is generally agreed that sugar, copper, rubber, food and oil industries have seen their worst and are near the turning point. It may be said with a considerable degree of assurance that the cotton and leather industries are liquidated to the bone and are ready to recover. The woolen and textile trades are on the road to a general recovery. This is evidenced by reports of increasing business in mercantile lines throughout the country. Readjustments downward are expected to continue in labor, coal and steel and probably in the automotive trades. On the whole, it may be said that readjustment is now in its final stage. That which remains to be readjusted can undoubtedly be accomplished without disturbance to the general industrial fabric. It is well to consider that at the beginning of the year it did not seem possible that by this time prices for raw materials would have reached the point of approximate stabilization; that wage reductions would have been accepted by workers in widely diversified industries in the realization that they were just and necessary and finally that the banking position as a whole could have improved to the extent indicated by the substantial reduction in the borrowings of reporting member banks at the Federal Reserve banks. Borrowings, in general, have declined close to 50 per cent from the maximum reached last fall. Sentiment in regard to business will naturally fluctuate in times like these. The reaction from the spurt in spring business has caused profound disappointment. On the other hand, it is unwise to expect other than quiet business during the summer months.

CHEMICALS

An irregular weakness was noted in the market on *bichromate of soda* on spot, and a few small lots were disposed of below 8c. per lb. At the closing the feeling was somewhat steadier and prices ranged all the way from 8@8½c. per lb., with 8½c. the general quotation for standard goods ex-store. Trading has not shown much activity, and the slow inquiry inspired a keener state of competition among small holders in an effort to stimulate business. Quiet trading in spot *bichromate of potash* was reported by dealers during the past week at 11½@12¼c. per lb. Offerings continue limited on spot, but seem to be sufficient to cover the quiet extent of demand at present. There has been no material change in this chemical for several weeks. Imported *caustic potash*, 88-92 per cent, of German manufacture is on the market at prices ranging from 5@5½c. per lb., depending upon the quantity and seller. Dealers have placed an irregular business in this chemical and the price compares with 4½c. which was quoted just prior to the war when the market was recovering from one of the keenest trade wars ever experienced in this commodity. Foreign *chlorate of potash* has been offered in the local market on the basis of 7½@8c. per lb. and at 7c. per lb. for shipment from Germany, duty paid. At the close it was stated that this figure might be shaded on account of a decline in exchange rates. Prime American material continues unchanged at 12c. per lb. f.o.b. works. Resale *caustic soda* has been well sustained throughout the entire week at \$4.10 per 100 lb. and upward for standard brands. Offerings have not been so plentiful and there was enough inquiry noted to keep prices firm. Demand has involved the wants of both domestic and foreign consumers and some sales for export went through at 4½c. per lb. Producers are firm on contracts at 3½c. per lb., basis 60 per cent, f.o.b. works. Large dealers of *nitrite of soda* have quoted the market at 7½@8c. per lb. on spot during most of the week. Small lots have changed hands below the inside figure and irregular business has been reported down to 7½c. per lb. The market is being carefully watched and holders have not lost confidence in price prospects. It is asserted that any permanent improvement in demand will likely find response in the course of values. Dealers in im-

ported *prussiate of soda* have quoted 12½@12¾c. per lb. on spot during the week, but it is stated that very little business took place below the outside figure. At the close an isolated lot might have been purchased at 12¾c., but the market in most directions was quoted as steady at 12½c. per lb. Small-lot transactions were about the best that could be noted in this market. Resale *soda ash* in single bags has been well maintained at \$2.15 per 100 lb. and dealers have made sales at this figure and upward to \$2.20, depending on quantity. Barrels have sold as high as 2¾c. per lb. in less than carload lots and down to \$2.55 per 100 lb. in carlots. At the works prices held at \$1.60 per 100 lb. for single bags, basis 48 per cent, and \$1.95 per 100 lb. for barrels, basis 48 per cent.

COAL-TAR PRODUCTS

Reports from various quarters of the coal-tar products market during the past week show different degrees of improvement, but on the whole a more active interest is noted among consumers and moderate sized lots are moving to meet requirements of the present and near future. The consuming demand for *paranitraniline* was very light and prices ranged from 85c.@\$1 per lb., depending on seller and quantity. *Benzene* showed the same active conditions that have been noted for some time. Supplies seem to be quite limited and prices firm. The balance of the crude products were dull and only small quantities moved at irregular intervals. *Aniline oil* is moving in limited volume and prices are steady at 20@26c. per lb. *Beta naphthol* is firm at 38@40c. per lb. and fairly active. Supplies of dimethylaniline are limited, while the demand is fair and prices steady at 40@50c. per lb., depending on seller. *Meta-phenylenediamine* was in fair request and supplies were quotably unchanged at \$1.15@\$1.20 per lb. The market on *benzaldehyde* is reported dull with only a routine business of small volume. Prices have shown no recent change, with the technical quoted at 45@50c. per lb. and the U.S.P. at \$1.50 per lb. Reports from some quarters show an improvement in the consuming demand for *benzoic acid* with the U.S.P. moving on a basis of 60@65c. per lb. and the technical type at 50@60c. per lb. Available supplies are low. There has been very little change in the limited volume of business in *diphenylamine*, but the principal factors are steady in their views at 65c. per lb., while the low-priced resale lots are believed to be quite well absorbed. The past week has revealed little in *alphanaphthylamine* that could be construed as an improved outlook for an active market. There have been no changes in prices, however, which are quoted at 35@40c. per lb.

VEGETABLE OILS

Textile mills have been taking fair quantities of the technical grades of *castor oil*. Lubricant houses have not been active. In the U.S.P. grade the market was quiet but unchanged at 10c. per lb. Scattered parcels of *chinawood oil* sold in the past week at prices ranging from 14@15c. per lb. The offerings were comparatively light and quotations at all times were more or less nominal. Interest was noted in nearby stuff, but the ideas of buyers were somewhat below those of sellers. It was reported that 10¾c. might be done on July-August arrival at N. Y. For July-August shipment from the Orient 10¼c. could have been done. Closing prices in the market on *coconut oil* showed very little change compared with a week ago, yet the undertone in some directions was barely steady, due to a general lack of buying interest. Ceylon grade oil was unchanged on the spot at 10¼c. per lb. in barrels, with the Cochin type oil quoted at 11@11½c. per lb. There was a firmer market for crude *corn oil* in the West in sympathy with the strength in other competing oils. Demand, however, for immediate shipment remained quiet. At the close holders were asking 5¾@6c. per lb. for shipment. Crude oil in N. Y. held at 7½@7¾c. per lb. Further weakness in tallow did not help the *palm oil* situation. Exchange again was easier, but not so as to influence sellers, for closing prices showed little if any change compared with quotations of a week previous. *Lagos oil* for shipment was offered at 6½c. per lb. c.i.f. N. Y. *Lagos oil* on spot was regarded steady at 7c. per lb. Holders of crude *peanut oil* throughout the South were rather firm in their ideas,

yet a lack of important buying checked attempts to advance prices. At the close prime oil was available at 6c. per lb., buyers' tanks, f.o.b. mill with strictly prime material at 6¼c. It was reported that scattered business went through at 6c. per lb.

The Chicago Market

CHICAGO, Ill., June 29, 1921.

There was a noticeable improvement in the tone of the industrial chemical market during the past two weeks. All quarters reported an increased volume of business, and while the quantities ordered are not large, the buyers are demanding immediate delivery, showing that supplies in consumers' hands are getting low. Prices as a rule are firm, with holders showing little or no disposition to cut. The small lots of foreign material on the market have had little effect on the domestic manufacturers, who seem to be holding their own.

GENERAL CHEMICALS

A firm tone still ruled in the market for *caustic soda*, although business was quieter. Supplies among second hands are small, and 4c. for solid 76 per cent and 4¾c. for the ground were the prevailing quotations. *Soda ash* is still very firm, and supplies could not be obtained under \$2.60 per 100 lb. for material in barrels. *Sal soda* seems to be moving quite well at \$1.65@\$1.70 per 100 lb., although no large orders were reported. *Sal ammoniac* is unchanged as to price and is not moving so well. Prime white material, 98-100 per cent, is available at 8½c. per lb. in single casks. *Blue vitriol* is very firm, with prices ranging from 6c.@7c. per lb. according to the holder and the package. A fair movement of *carbon bisulphide* was noted in some quarters and supplies were available at 7½c.@8c. per lb. *Epsom salts* were in fair request and prices were firm at 3c.@3¼c. per lb. for the U.S.P. in barrels. *Formaldehyde* was very quiet and few sales were reported. Supplies are plentiful at 14c. per lb. for single barrels.

The *glycerine* market is very quiet, with little material moving. Offers as low as 15½c. per lb. were reported, but the prevailing price was 15¾c. for large drums. *Potassium bichromate* is quiet and steady, with a few small sales noted. Material of standard brand is offered at 14c.@14½c. per lb. according to the seller. *Sodium bichromate* is not moving so well and supplies are available at 9c.@9½c. for single casks. *Bicarbonate of soda* is in fair request, and dealers are asking \$2.65@\$2.75 per 100 lb. for a good grade of material. *Hyposulphite of soda* is moving very well and the price is firm at \$3.85 per 100 lb. *Sodium nitrite* is one of the firmest items on the list, and 9c. was the lowest offer noted.

ACIDS

As a rule the list of acids is quiet and unchanged. The demand for *citric acid* is rather disappointing for this time of year, and in some quarters supplies are heavy. Second hands are quoting as low as 45c. in some instances. *Oxalic acid* is quiet, and supplies are available at 18c.@20c. per lb. *Tartaric acid* is weak, and offerings at 32c. per lb. were heard. The heavy acids are quiet and unchanged as to price. *Sulphuric*, 66 deg., is quoted by makers at \$19@\$20 per ton in tank cars f.o.b. works.

VEGETABLE OILS

This market has shown more life during the past week than for several months. One dealer describes his business in *linseed oil* as fine, while several factors report a very good volume. In 10-bbl. lots or over the boiled oil is available at 80c. per gal., with a corresponding reduction for the raw.

NAVAL STORES

This branch of the trade has shown a decided change for the better and conditions are about all that could be expected. There is a good movement of turpentine and less than carlots are quoted at 60c. per gal., drum basis. The *rosins* are moving in a fair way, and prices are firm, with less than carlots quoted at \$6.60 per 280 lb. for the "G" grade. *Rosin oil* is also in fair request, and is offered at 45c. per gal. in barrels.

The Iron and Steel Market

PITTSBURGH, July 1, 1921.

The steel market has become still quieter, the absence of buying being almost complete, at least as regards the mills. There is more support to the theory that some of the buying is intercepted by manufacturing consumers reselling what stocks of steel they have remaining. There is evident a desire on the part of all consumers or distributors to reduce stocks not to the possible minimum but to absolute zero. The precise motive is not clearly understood, whether a fear that prices will decline greatly or a desire to be without stocks for an indefinite period. As in resales the mill market must be greatly undersold, the prospect of a further decline in steel prices is not necessarily a sufficient reason. Support to the theory that reselling is an important factor in reducing the demand on the mills is the fact that mills find demand for merchant steel bars especially light among steel products in general, and bars are a commodity that are normally stocked in considerable quantities, while stocks are mobile, since a consumer can generally be found for any ordinary section or size of bar.

DECLINING TENDENCY IN STEEL PRICES

There is a generally declining tendency in steel prices, but the fortuitous or occasional declines are of no great interest, while in the majority of commodities there is really no stable market price at any given time. There is so little business that while there is competition there is not enough to develop clear cut prices. The trade at large is not interested so much in current prices as in prospective prices, for it is generally understood that a definite price level will be furnished by the mills when they see that buying of any consequence is ready to occur and the buyer in his turn feels that he must be assured that he will not gain by deferring his purchase.

To illustrate the attitude, it is not uncommon for the buyer to ask the mill to guarantee a price to date of shipment of the steel, which is something the mills will not do, but if that is the mental attitude of the manufacturing consumer it is obvious that he thinks still more of the time that must elapse between the date of shipment of the steel and the date of sale of the goods he intends making from the steel, and at this time he cannot sell his product ahead. He does well if he makes sales out of stock already produced.

NEW STEEL CORPORATION PRICE SCHEDULE PREDICTED

In some quarters it is predicted that within a few weeks the United States Steel Corporation will announce a schedule of prices so low that it will be accepted as the minimum that buyers can expect, at least for a period of months, but this would be done only in case it seemed clear that there was a latent demand to be developed by price reduction. Up to this time the mills have claimed, with good show of reason, that buyers were not ready to take hold, no matter what prices were quoted.

The so-called "April prices" are down \$5 a ton in wire products and sheets, as noted in previous reports. Other steel commodities are being shaded more or less from the April schedule, but there is no formal announcement that the Steel Corporation has made departures other than in wire products and sheets. It is just learned that the corporation recently reduced the galvanizing differential in wire from 70c. to 50c. per 100 lb., so that with plain wire at 2.75c. galvanized wire is 3.25c., and with painted barb wire at 3.15c. galvanized barb wire is 3.65c. Nails are at \$3, as formerly announced.

PIG IRON AND COKE

Pig iron is practically nominal at last week's quotations: Bessemer, \$22.50; basic, \$20.50; foundry, \$31.50 f.o.b. valley furnaces, with \$1.96 freight to Pittsburgh. On an attractive inquiry these prices could be shaded, as with continued light absorption of stocks and prospects of the replacement cost decreasing furnaces are more anxious to liquidate.

Connellsville coke for spot shipment remains quotable at \$3 for furnace and \$4.25 to \$4.75 for foundry. On an attractive inquiry the furnace coke price could probably be shaded.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

	Carlots	Less Carlots
Acetic anhydride.....lb.	\$0.12½ - \$0.12½	\$0.40 - \$0.45
Acetone.....lb.	1.13 - 1.13	1.13 - 1.13

Brimstone (see sulphur, roll).....lb.	41 - 42	43 - 45
Bromine.....lb.	2.00 - 2.05	2.00 - 2.05
Calcium acetate.....100 lbs.	04½ - 04½	05 - 05½
Calcium carbide.....lb.	23.50 - 24.00	24.50 - 25.50
Calcium chloride, fused, lump.....ton	01½ - 02	02½ - 02½
Calcium chloride, granulated.....lb.	2.15 - 2.25	2.35 - 2.50
Calcium hypochlorite (bleach powder) 100 lb.....lb.	1.40 - 1.50	1.40 - 1.50
Calcium peroxide.....lb.	15 - 16	15 - 16
Calcium phosphate, tribasic.....lb.	75 - 78	75 - 78
Camphor.....lb.	06½ - 07	07½ - 08
Carbon bisulphide.....lb.	10½ - 10½	11 - 12
Carbon tetrachloride, drums.....lb.	60 - 75	60 - 75
Carbonyl chloride (phosgene).....lb.	07 - 07½	07½ - 08
Caustic potash (see potassium hydroxide).....lb.	07 - 07½	07½ - 08
Caustic soda (see sodium hydroxide).....lb.	07 - 07½	07½ - 08
Chlorine, gas, liquid-cylinders (100 lb.).....lb.	08 - 09	09 - 10
Chloroform.....lb.	40 - 43	40 - 43
Cobalt oxide.....lb.	3.00 - 3.10	3.00 - 3.10
Copperas (see iron sulphate).....lb.	20 - 21	22 - 23
Copper carbonate, green precipitate.....lb.	05½ - 06	06½ - 06½
Copper cyanide.....lb.	05½ - 06	06½ - 06½
Copper sulphate, crystals.....lb.	05½ - 06	06½ - 06½
Cream of tartar (see potassium bitartrate).....lb.	05½ - 06	06½ - 06½
Epsom salt (see magnesium sulphate).....lb.	05½ - 06	06½ - 06½
Ethyl Acetate Com. 85%.....gal.	05½ - 06	06½ - 06½
Ethyl Acetate pure (necetic ether 98% to 100%).....lb.	05½ - 06	06½ - 06½
Formaldehyde, 40 per cent.....lb.	13½ - 14	14 - 15
Fusel oil, ref.....gal.	3.00 - 3.25	3.00 - 3.25
Fusel oil, crude.....gal.	1.75 - 2.00	1.75 - 2.00
Glauber's salt (see sodium sulphate).....lb.	16 - 16½	16 - 16½
Glycerine, C. P. drums extra.....lb.	3.65 - 3.75	3.65 - 3.75
Iodine, resublimed.....lb.	10 - 20	10 - 20
Iron oxide, red.....lb.	19.00 - 20.00	21.00 - 22.00
Iron sulphate (copperas).....ton	11½ - 13½	11½ - 13½
Lead acetate.....lb.	09 - 09½	10 - 11
Lead arsenate, paste.....lb.	15 - 20	15 - 20
Lead nitrate.....lb.	08½ - 09	08½ - 09
Litharge.....lb.	1.30 - 1.40	1.30 - 1.40
Lithium carbonate.....lb.	09 - 09½	10 - 11
Magnesium carbonate, technical.....lb.	2.40 - 2.75	2.40 - 2.75
Magnesium sulphate, U. S. P.....100 lb.	1.20 - 1.75	1.20 - 1.75
Magnesium sulphate, technical.....100 lb.	07 - 80	07 - 80
Methanol, 95%.....gal.	80 - 85	80 - 85
Methanol, 97%.....gal.	14 - 14½	14 - 14½
Nickel salt, double.....lb.	15 - 15½	15 - 15½
Nickel salt, single.....lb.	15 - 15½	15 - 15½
Phosgene (see carbonyl chloride).....lb.	45 - 46	47 - 50
Phosphorus, red.....lb.	35 - 37	35 - 37
Phosphorus, yellow.....lb.	11½ - 12	12½ - 12
Potassium bichromate.....lb.	11½ - 12	12½ - 12

	Carlots	Less Carlots
Potassium bitartrate (cream of tartar)..... lb.	\$. . . - \$. . .	\$0.30 - \$0.31
Potassium bromide, granular..... lb.	.35 - .40	.16 - .25
Potassium carbonate, U. S. P..... lb.	.35 - .40	.45 - .50
Potassium carbonate, 80-85%..... lb.	.05 - .051	.06 - .07
Potassium chlorate, crystals..... lb.	.07 - .071	.08 - .12
Potassium cyanide..... lb.	.05 - .051	.26 - .28
Potassium hydroxide (caustic potash)..... lb.	.05 - .051	.051 - .06
Potassium muriate, 80% K.C.L..... ton	49.00 - 50.00	
Potassium iodide..... lb.		2.75 - 3.00
Potassium nitrate..... lb.	.091 - .091	.10 - .121
Potassium permanganate..... lb.	.29 - .30	.31 - .32
Potassium prussiate, red..... lb.	.35 - .37	.38 - .40
Potassium prussiate, yellow..... lb.	.241 - .25	.251 - .26
Potassium sulphate (powdered)..... per unit		1.50 - 1.75
Rochelle salts (see sodium potas tartrate).....		
Salammoniac (see ammonium chloride).....		
Sal soda (see sodium carbonate).....		
Salt cake..... ton		27.00 - 30.00
Silver cyanide..... oz.		1.35 - 1.38
Silver nitrate..... oz.		.40 - .41
Soda ash, light..... 100 lb.	2.15 - 2.20	2.30 - 2.70
Soda ash, dense..... 100 lb.	2.40 - 2.45	2.50 - 2.75
Sodium acetate..... lb.	.041 - .041	.041 - .051
Sodium bicarbonate..... 100 lb.	2.25 - 2.40	2.50 - 2.75
Sodium bichromate..... lb.	.08 - .081	.081 - .09
Sodium bisulphate (nitre cake)..... ton	5.00 - 5.25	5.50 - 6.50
Sodium bisulphite powdered, U.S.P..... lb.	.05 - .051	.051 - .06
Sodium borate (borax)..... lb.	.06 - .061	.061 - .07
Sodium carbonate (sal soda)..... 100 lb.	1.90 - 2.00	2.10 - 2.40
Sodium chlorate..... lb.	.071 - .071	.08 - .081
Sodium cyanide..... lb.	.191 - .21	.22 - .30
Sodium fluoride..... lb.	.111 - .12	.121 - .131
Sodium hydroxide (caustic soda)..... 100 lb.	4.15 - 4.25	4.30 - 4.80
Sodium hyposulphite..... lb.		.031 - .031
Sodium nitrate..... 100 lb.	2.80 - .	3.00 - .
Sodium nitrite..... lb.	.071 - .071	.071 - .08
Sodium peroxide, powdered..... lb.	.25 - .26	.27 - .30
Sodium phosphate, dibasic..... lb.	.041 - .041	.05 - .051
Sodium potassium tartrate (Rochelle salts) lb.		.26 - .27
Sodium prussiate, yellow..... lb.	.121 - .121	.13 - .131
Sodium silicate, solution (40 deg.)..... lb.	1.00 - 1.15	1.25 - 1.40
Sodium silicate, solution (60 deg.)..... lb.	.021 - .03	.031 - .031
Sodium sulphate, crystals (Glauber's salt) 100 lbs.	1.50 - 1.75	2.00 - 2.25
Sodium sulphide, fused, 60-62 per cent (conc.) lb.	.051 - .051	.06 - .061
Sodium sulphite, crystals..... lb.	.031 - .04	.041 - .041
Strontium nitrate, powdered..... lb.	.15 - .151	.16 - .17
Sulphur chloride, red..... lb.	.07 - .071	.071 - .08
Sulphur, crude..... ton	20.00 - 22.00	
Sulphur dioxide, liquid, cylinders extra..... lb.	.08 - .081	.09 - .10
Sulphur (sublimed), flour..... 100 lb.		2.25 - 3.10
Sulphur, roll (brimstone)..... 100 lb.		2.00 - 2.75
Tin bichloride, 50 per cent..... lb.	.18 - .19	
Tin oxide..... lb.		.40 - .42
Zinc carbonate, precipitate..... lb.	.16 - .18	.19 - .20
Zinc chloride, gran..... lb.	.11 - .111	.111 - .12
Zinc cyanide..... lb.	.45 - .49	.50 - .60
Zinc dust..... lb.	.111 - .111	.111 - .121
Zinc oxide, XX..... lb.	.09 - .091	.091 - .10
Zinc sulphate..... 100 lb.	2.90 - 3.00	3.25 - 3.75

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude..... lb.	\$1.10 - \$1.15
Alpha-naphthol, refined..... lb.	1.25 - 1.30
Alpha-naphthylamine..... lb.	.35 - .40
Aniline oil, drums extra..... lb.	.20 - .27
Aniline salts..... lb.	.26 - .29
Anthracene, 80% in drums (100 lb.)..... lb.	.75 - 1.00
Benzaldehyde U.S.P..... lb.	1.50 - .
Benzidine, base..... lb.	.85 - 1.00
Benzidine sulphate..... lb.	.75 - .85
Benzoic acid, U.S.P..... lb.	.60 - .65
Benzoate of soda, U.S.P..... lb.	.55 - .60
Benzene, pure, water-white, in drums (100 gal.) gal.	.27 - .32
Benzene, 90%, in drums (100 gal.)..... gal.	.25 - .28
Benzyl chloride, 95-97%, refined..... lb.	.28 - .30
Benzyl chloride, tech..... lb.	.20 - .25
Beta-naphthol benzoate..... lb.	3.50 - 4.00
Beta-naphthol, sublimed..... lb.	.70 - .75
Beta-naphthol, tech..... lb.	.38 - .40
Beta-naphthylamine, sublimed..... lb.	1.75 - 1.80
Cresol, U. S. P., in drums (100 lb.)..... lb.	.16 - .18
Ortho-cresol, in drums (100 lb.)..... lb.	.25 - .27
Cresylic acid, 97-99%, straw color, in drums..... gal.	.70 - .80
Cresylic acid, 35-97%, dark, in drums..... gal.	.65 - .70
Cresylic acid, 50%, first quality, drums..... gal.	.45 - .50
Dichlorobenzene..... lb.	.06 - .09
Diethylaniline..... lb.	1.20 - 1.25
Dimethylaniline..... lb.	.40 - .50
Dinitrobenzene..... lb.	.26 - .28
Dinitrochlorobenzene..... lb.	.20 - .30
Dinitronaphthalene..... lb.	.30 - .40
Dinitrophenol..... lb.	.35 - .40
Dinitrotoluene..... lb.	.27 - .30
Dip oil, 25%, car lots, in drums..... gal.	.40 - .45
Diphenylamine..... lb.	.60 - .65
H-acid..... lb.	1.20 - 1.30
Meta-phenylenediamine..... lb.	1.15 - 1.20
Monochlorobenzene..... lb.	.12 - .14
Monoethylaniline..... lb.	1.75 - 1.85
Naphthalene crushed, in obls..... lb.	.07 - .081
Naphthalene, flake..... lb.	.07 - .081
Naphthalene, balls..... lb.	.081 - .091
Naphthionic acid, crude..... lb.	.70 - .75
Nitrobenzene..... lb.	.12 - .15
Nitro-naphthalene..... lb.	.30 - .35
Nitro-toluene..... lb.	.16 - .18
Ortho-amidophenol..... lb.	3.10 - 3.20
Ortho-dichlor-benzene..... lb.	.15 - .20
Ortho-nitro-phenol..... lb.	.80 - .85
Ortho-nitro-toluene..... lb.	.15 - .20
Ortho-toluidine..... lb.	.20 - .25
Para-amidophenol, base..... lb.	1.50 - 1.60
Para-amidophenol, HCl..... lb.	1.75 - 1.80

Para-dichlorobenzene..... lb.	.15 - .20
Paranitroniline..... lb.	.85 - 1.00
Para-nitrotoluene..... lb.	.85 - .95
Para-phenylenediamine..... lb.	1.75 - 2.00
Para-toluidine..... lb.	1.25 - 1.40
Phthalic anhydride..... lb.	.50 - .60
Phenol, U. S. P., drums..... lb.	.11 - .13
Pyridine..... gal.	2.00 - 3.50
Resorcinol, technical..... lb.	1.75 - 1.85
Resorcinol, pure..... lb.	2.25 - 2.30
Silicic acid, tech., in bbls..... lb.	.19 - .22
Salicylic acid, U. S. P..... lb.	.20 - .25
Salol..... lb.	.80 - .85
Solvent naphtha, water-white, in drums, 100 gal gal.	.25 - .28
Solvent naphtha, crude, heavy, in drums, 100 gal gal.	.14 - .16
Sulphanilic acid, crude..... lb.	.30 - .35
Toluidine..... lb.	1.25 - 1.35
Toluidine, mixed..... lb.	.40 - .45
Toluene, in tank cars..... gal.	.25 - .28
Toluene, in drums..... gal.	.28 - .31
Xylidines, drums, 100 gal..... lb.	.40 - .45
Xylene, pure, in drums..... gal.	.40 - .45
Xylene, pure, in tank cars..... gal.	.45 - .
Xylene, commercial, in drums, 100 gal..... gal.	.33 - .35
Xylene, commercial, in tank cars..... gal.	.30 - .

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark..... lb.	\$0.24 - \$0.25
Beeswax, refined, light..... lb.	.27 - .28
Beeswax, white pure..... lb.	.42 - .45
Carnauba, Florida..... lb.	.58 - .60
Carnauba, No. 2, North Country..... lb.	.25 - .26
Carnauba, No. 3, North Country..... lb.	.151 - .16
Japan..... lb.	.17 - .171
Montan, crude..... lb.	.061 - .061
Paraffine waxes, crude match wax (white) 105-110 m.p..... lb.	.031 - .031
Paraffine waxes, crude, scale 124-126 m.p..... lb.	.021 - .031
Paraffine waxes, refined, 118-120 m.p..... lb.	.031 - .031
Paraffine waxes, refined, 125 m.p..... lb.	.041 - .041
Paraffine waxes, refined, 128-130 m.p..... lb.	.041 - .05
Paraffine waxes, refined, 133-135 m.p..... lb.	.051 - .051
Paraffine waxes, refined, 135-137 m.p..... lb.	.051 - .06
Stearic acid, single pressed..... lb.	.09 - .
Stearic acid, double pressed..... lb.	.091 - .
Stearic acid, triple pressed..... lb.	.10 - .101

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl..... 280 lb.	\$5.00 - .
Rosin E-I..... 280 lb.	5.30 - 5.50
Rosin K-N..... 280 lb.	5.70 - 6.50
Rosin W. G. W. W..... 280 lb.	6.60 - .
Wood rosin, bbl..... 280 lb.	6.25 - .
Spirits of turpentine..... gal.	.581 - .
Wood turpentine, steam dist..... gal.	.50 - .
Wood turpentine, dest. dist..... gal.	.54 - .
Pine tar pitch, bbl..... 200 lb.	. - 6.75
Tar, kiln burned, bbl. (500 lb.)..... bbl.	. - 11.50
Retort tar, bbl..... 500 lb.	. - 11.50
Rosin oil, first run..... gal.	.35 - .
Rosin oil, second run..... gal.	.38 - .
Rosin oil, third run..... gal.	.43 - .
Pine oil, steam dist., sp.gr. 0.930-0.940..... gal.	\$1.80 - .
Pine oil, pure, dest. dist..... gal.	1.50 - .
Pine tar oil, ref., sp.gr. 1.025-1.035..... gal.	.46 - .
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla..... gal.	.35 - .
Pine tar oil, double ref., sp.gr. 0.965-0.990..... gal.	.75 - .
Pine tar, ref., thin, sp.gr. 1.080-1.960..... gal.	.35 - .
Turpentine, crude, sp. gr. 0.900-0.970..... gal.	1.20 - .
Hardwood oil, f.o.b. Mich., sp.gr. 0.960-0.990..... gal.	.35 - .
Pinewood creosote, ref..... gal.	.52 - .

Solvents

73-76 deg., steel bbls. (85 lb.)..... gal.	\$0.41 - .
70-72 deg., steel bbls. (85 lb.)..... gal.	.39 - .
68-70 deg., steel bbls. (85 lb.)..... gal.	.38 - .
V. M. and P. naphtha, steel bbls. (85 lb.)..... gal.	.30 - .

Crude Rubber

Para-Upriver fine..... lb.	\$0.16 - .17
Upriver coarse..... lb.	.09 - .091
Upriver caucho ball..... lb.	.111 - .12
Plantation—First latex crepe..... lb.	.141 - .
Ribbed smoked sheets..... lb.	.12 - .121
Brown crepe, thin, clean..... lb.	.15 - .
Amber crepe No. 1..... lb.	.17 - .

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls..... lb.	\$0.081 - \$0.09
Castor oil, AA, in bbls..... lb.	.10 - .101
China wood oil, in bbls. (f.o.b. Pac. coast)..... lb.	.141 - .15
Cocoonut oil, Ceylon grade, in bbls..... lb.	.101 - .101
Cocoonut oil, Cochín grade, in bbls..... lb.	.11 - .111
Corn oil, crude, in bbls..... lb.	.071 - .071
Cottonseed oil, crude (f. o. b. mill)..... lb.	.051 - .051
Cottonseed oil, summer yellow..... lb.	.071 - .08
Cottonseed oil, winter yellow..... lb.	.08 - .
Linseed oil, raw, car lots (domestic)..... gal.	.73 - .75
Linseed oil, raw, tank cars (domestic)..... gal.	.67 - .
Linseed oil, in 5-bbl. lots (domestic)..... gal.	.75 - .77

Olive oil, Denatured.....	gal	\$1.55	—	\$1.45
Palm, Lagos.....	lb.	.05	—	.07
Palm, Niger.....	lb.	.05 ¹ ₂	—	.05 ¹ ₂
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.06	—	.06 ¹ ₂
Peanut oil, refined, in bbls.....	lb.	.10	—	.10 ¹ ₂
Rapeseed oil, refined in bbls.....	gal.	.88	—	.90
Rapeseed oil, blown, in bbls.....	gal.	.94	—	.95
Soya bean oil (Manchurian), in bbls. N. Y.....	lb.	.07 ³ ₄	—	—
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.05 ¹ ₄	—	—

FISII

Light pressed menhaden.....	gal.	\$0.42	—	
Yellow bleached menhaden.....	gal.	.44	—	
White bleached menhaden.....	gal.	.46	—	
Brown menhaden.....	gal.	.50	—	

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.	net ton	\$24.00	—	30.00
Barytes, ground, off color, f.o.b. Kings Creek	net ton	22.00	—	26.00
Barytes, crude, 88% @ 94% ba., Kings Creek	net ton	10.00	—	12.00

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

PINEY POINT—The Florida Oil Refining Association, Tampa, Fla., has preliminary plans in preparation for the erection of a new refinery at Piney Point. A local tract, comprising about 1,100 acres of land, has been acquired as a site; the plant will be of two-unit type, with daily output of about 2,000 bbl. A storage capacity of 80,000 bbl. will be provided. The new plant is estimated to cost about \$250,000, including equipment.

Arkansas

EL DORADO—The Union Pipe Line & Refining Co. has completed a new local refinery and operations have been inaugurated. The plant is of 5,000-bbl. capacity and will handle crude oil from this district exclusively. The company has another refining plant under construction, and plans to have the unit ready for service early in August.

California

LOS ANGELES—The Bradley-Wise Paint Co., 650 Santa Fe Ave., has arranged for an increase in capital from \$50,000 to \$150,000, and has tentative plans under way for the establishment of a new plant. It is said that a number of local sites are being considered.

SAN JOSE—The plant of the Fred Cooke Oil Co. was partly destroyed by fire, June 11, with loss estimated at about \$30,000. The company is reported to be planning for early rebuilding.

LOS ANGELES—C. H. Winkelman, formerly president and general manager of the California Varnish Co., has organized a company to be known as C. H. Winkelman & Co., to operate a plant at 2416-26 San Leandro St., for the manufacture of paints, enamels, varnishes, etc. P. M. Waldron will act as factory superintendent.

SUMMERLAND—The Department of Agriculture, Washington, D. C., has taken bids for the sale of the Government kelp potash plant here. The highest bid received, totaling \$35,000, is said to be irregular and not in accord with conditions. The next highest bid, for \$25,000, was made by M. E. Saville, San Francisco.

LOS ANGELES—The Republic Steel Package Co., 7930 Jones Rd., has acquired property here for the erection of a new plant for Pacific Coast service. The initial plant unit will be 60 x 300 ft., and will be equipped to give employment to about 100 operatives. S. B. Merry is treasurer.

Idaho

BOISE—Edward Crassen, Baker, Ore., and associates are considering the erection of a new plant in the vicinity of Boise for the manufacture of paint, varnish, etc.

Illinois

CHICAGO—The Carbo Oxygen Co., affiliated with the Carbo Hydrogen Co., 10305 Torrence Ave., has construction under way on a new plant at 10329-41 Torrence Ave., to be 1-story, 55 x 140 ft., and estimated to cost about \$18,000. W. G. Langenheim, 333 South Dearborn St., is engineer.

Indiana

CHESTERTON—The United States China Co. will soon commence the erection of an addition to its local plant, to comprise a number of buildings. A new main 2-story structure, 100 x 300 ft., will be built, with adjoining building, 50 x 50 ft., to be equipped as a sagger manufacturing department. Five new kilns will be constructed, the work is estimated to cost close to \$100,000.

INDIANAPOLIS—The Standard Oil Co. of Indiana is completing negotiations for the purchase of the Midwest Refining Co., the acquisition to include all oil refineries and other property. The Standard company

recently increased its capital from \$100,000,000 to \$140,000,000. A large portion of the increase, it is said, will be used for the proposed purchase.

Louisiana

SHREVEPORT—The plant of the Henderson Cotton Oil Co. was destroyed by fire, June 22, with loss estimated at \$300,000, including machinery. A number of buildings sustained a large loss, including main mill and lint department.

Maryland

BALTIMORE—The Zirconium Co. of America, Monument and Eleventh Sts., recently organized to manufacture ferrozirconium and other products, will install an electrochemical plant at its new works for oxide production. George F. Dixon is president.

BEL AIR—The Maryland Flint & Feldspar Co. has perfected plans for the construction of a new plant near Bel Air, to replace its present works. It is estimated to cost about \$250,000, including machinery.

BALTIMORE—The Rasin-Monumental Co., National Marine Bldg., is arranging preliminary plans for the erection of its proposed new fertilizer manufacturing plant on Fairfield St., estimated to cost close to \$1,000,000 with machinery. The plant will be used as an extension to the company's works in the Curtis Bay section.

BALTIMORE—The International Chemical Products Co., 13 West Saratoga St., recently organized, has plans under way for the erection of a new plant for the manufacture of pulp and paper products, extracts, etc. Six buildings will be erected at a cost of about \$25,000, and machinery and equipment estimated to cost \$75,000 installed. The latter will include extracting, evaporating, refining and other apparatus. The company is capitalized at \$150,000. W. A. Gardner is president, and Frank L. La Motte secretary.

BALTIMORE—The Gwynns Falls Paper Co., 517 Calvert Bldg., has taken title to property in the Gwynns Falls section, comprising about 5 acres of land, as a site for the erection of its proposed new paper mill, estimated to cost about \$250,000 with machinery. Joseph H. Wallace & Co., 5 Beekman St., New York, are engineers. George W. Davis is head.

Massachusetts

SPRINGFIELD—The Springfield Bronze Foundry Co. has awarded a contract to the M. J. O'Connell Co., 23 Murray Hill St., for the erection of its proposed new foundry for the manufacture of brass and bronze castings, at 166 Charles St. It will be 40 x 50 ft.

Michigan

DETROIT—Parke, Davis & Co., 2951 Atwater St., manufacturer of chemicals, etc., has construction under way on a new 2-story building, 100 x 200 ft., to cost about \$60,000. Frank H. Davis, 1838 Penobscot Bldg., has the erection contract.

Missouri

ST. LOUIS—The Chester Iron & Foundry Co., 7800 Vulcan St., has taken bids for the erection of a new 1-story foundry and plant addition, 45 x 117 ft., to cost about \$40,000. A. J. Schaelich is president.

ST. LOUIS—The Fleischmann Yeast Co., 1535 Market St., has awarded a contract to Kremer & Voirol, St. Louis, for the erection of its proposed new 1-story plant on the Forest Park Blvd., near Bogle Ave., 75 x 170 ft., estimated to cost about \$50,000.

Montana

WINNET—The Southern Alberta Refineries, Ltd., Calgary, Alta., is planning for the erection of a new oil refinery at Winnett. A site has been acquired and the proposed plant is estimated to cost about \$100,000. William Livingston is president.

Nevada

TONOPAH—The West End Chemical Co., affiliated with the West End Consolidated Mines Co., headed by F. G. (Doc) Smith, San Francisco, Cal., is planning for the early operation of a new plant in southern Nevada for the production of refined borax. The company has an extensive colemanite deposit in this section and will develop the property on a large scale.

New Jersey

EDGEWATER—The Archer-Daniels-Lesseed Co., Twenty-ninth Ave., Minneapolis, Minn., is completing plans for the erection of its proposed new linseed oil works on property recently acquired at Edgewater. It is understood that bids for erection and equipment will be asked at an early date.

TRENTON—A creditors' committee, headed by Edgar W. Hunt, Trenton, has acquired the local plant of the Trent Rubber Co., Enterprise Ave., for a consideration said to be \$100,000, and will continue the plant in operation.

Ohio

DOVER—The Harbison-Walker Refractories Co., Pittsburgh, Pa., has disposed of its local clay properties to S. A. McCaskey, said to represent the Wayne Coal Co., which proposes to operate on the site. The property is located in the Strasburg section, and was sold for a consideration said to be \$40,000.

CLEVELAND—The Empire Rolling Mill Co., Bessemer Ave., and the Pennsylvania R.R., has commenced the erection of a new 1-story building at its plant, to be used as a steel-galvanizing works. With warehouse building to be constructed, it is estimated to cost about \$50,000. C. G. Berkwell is president.

Pennsylvania

ERIE—The Keystone Rubber Mfg. Co., 1413 East Eleventh St., manufacturer of mechanical rubber goods, is taking bids for the rebuilding of its plant, recently destroyed by fire with loss estimated in excess of \$100,000. It will be 3-story, 123 x 165 ft. J. M. Blake, Commercial Bldg., is engineer.

Tennessee

ANDERSON—The Robinson Lime Co., recently organized with a capital of \$250,000, has plans under way for the erection of a new lime-manufacturing plant on local site, with initial daily output of about 50 tons. Complete grinding and crushing departments will be installed. A. J. Robinson is president and M. H. Bates treasurer.

Texas

HOUSTON—James A. Harley, Houston, is organizing a local company to establish a new plant in the Bethany-Elvian gas field, Harrison Co., for the production of carbon black. The proposed works are estimated to cost in excess of \$500,000 with machinery.

BRIDGEPORT—The Edmonds Oil & Refining Co. has acquired the refinery of the Bridgeport Refining Co., and has plans under way for extensions and improvements for increased production.

COMMERCE—The Trinity Paper Mills Co., which recently commenced operations at a new local mill for the manufacture of paper pulp from cottonseed linters, is considering preliminary plans for the construction of branch mills for similar production at Fort Worth and McKinney, Tex.

BROWNWOOD—The Texas Oil & Gas Refineries Co., recently reorganized, is planning for the installation of additional equipment for gasoline production. Philip J. Baney is president and general manager.

Utah

SALT LAKE CITY—The Utah Oil Refining Co. is planning for the rebuilding of its plant, destroyed by fire, June 11, with loss reported in excess of \$500,000, including buildings and equipment.

Virginia

WINCHESTER—The Cornwell Lime-Marl Co. has plans in preparation for the erection of a new plant 25 x 68 ft. and 25 x 90 ft., with initial daily capacity of about 125 tons of lime marl. The plant will cost about \$25,000. C. J. Swank is general manager.

ROANOKE—The Viscose Co., Marcus Hook, Pa., manufacturer of artificial silk products, is reported to be planning for the erection of additions to its local plant, to double the present output.

New Companies

THE F. W. MUIR BOARD Co., Morristown, N. J., has been incorporated with a capital of \$100,000 to manufacture paperboard products. The incorporators are Franklin W. Muir, Robert H. McLeod and Oliver K. Day, Park Place, Morristown.

MARTIN-WALSH, INC., New York, N. Y., has been incorporated with a capital of \$70,000 to manufacture paper products. The incorporators are W. Martin, A. R. and J. C. Walsh, Jr. The company is represented by O. M. Bate, 26 Liberty St.

THE SPRINGFIELD WIRE & TINSEL Co., Springfield, Mass., has been incorporated with a capital of \$600,000 to manufacture wire products and kindred specialties. Gerald J. Callahan is president; and Edward S. Bradford, Springfield, treasurer.

THE MARK DELISSER CORP., New York City, has been incorporated with a capital of \$100,000 to manufacture chemicals and affiliated products. The incorporators are Mark Delisser, J. Dubow and M. B. Lesser, 132 Nassau St.

THE SERVICE PAINT & VARNISH WORKS, INC., Brooklyn, N. Y., has been incorporated with a capital of \$10,000 to manufacture paints, varnishes, etc. The incorporators are C. A. and J. C. Osterholm, W. D. MacNaughton, and J. A. Johnson, 91 Kenmore Pl., Brooklyn.

THE LUDINGTON NOVELTY MFG. Co., Ludington, Mich., has been incorporated with a capital of \$50,000 to manufacture steel needles and kindred products. The incorporators are Bernard Ostendorf, L. E. Vorse, and William C. Killen, Ludington.

THE SEPOY DYE PRODUCTS CORP., New York City, has been incorporated with a capital of \$150,000 to manufacture chemicals, dyestuffs, etc. G. Bothamley, 77 Pine St., is the principal incorporator.

THE UNITED STATES PORCELAIN Co., Trenton, N. J., has been incorporated with a capital of \$100,000, to manufacture porcelain wares and other ceramic products. The incorporators are John Janus and Carl Markau, 54 Seward Ave.

THE SOBOS OIL CORP., New York City, has been incorporated with a capital of \$16,000 to manufacture oil products. The incorporators are W. Davis, A. Conant, and W. C. Arnold, 120 B'way.

THE OZARK PETROLEUM Co., Willow Springs, Mo., has been incorporated with a capital of \$200,000 to manufacture petroleum products. L. O. Neider is president; and Dr. S. E. Haycraft, vice-president, both of Willow Springs.

THE CLARKSVILLE SEED Co., Clarksville, Tenn., has been incorporated with a capital of \$35,000 to manufacture cottonseed oil specialties. The incorporators are F. A. Antone and R. Isbell, Clarksville.

THE MOBILE PAINT MFG. Co., Mobile, Ala., has been incorporated with a capital of \$50,000 to manufacture paints, varnishes, etc. W. A. Benson is president; H. R. Luscher, treasurer; and Carter Luscher, secretary, all of Mobile.

DYAS & LEGRS, INC., 5514 West Lake St., Chicago, Ill., has been incorporated with a capital of \$15,000 to manufacture chemicals and chemical byproducts. The incorporators are Clair S. Dyas and Emil A. LeGros.

THE O. C. BARBER LIME Co., Room 48, 10 South St., Baltimore, Md., has been incorporated with a capital of \$600,000 to manufacture lime products. The incorporators are Clarence W. Perkins, Addison E. Hook and Mullin Wilson.

THE SHEPHERD CHEMICAL Co., New York City, has been incorporated with a capital of \$30,000 to manufacture chemicals, insecticides and kindred products. The incorporators are N. P. Cullom, F. B. Ryan and E. C. Dickinson. The company is represented by Cullom & Rinke, 165 B'way.

THE MONTVILLE PAPER Co., Montville, Conn., has been incorporated with a capital of \$50,000 to manufacture and deal in paper, paper boxes and affiliated specialties. The incorporators are R. C. Burchard, Montville; F. W. Mercer and F. L. McGuire, 64 Huntington St., New London, Conn.

THE SHAWMUT DRUG & CHEMICAL Co., Boston, Mass., has been incorporated with a capital of \$10,000 to manufacture chemical products. Joseph M. McManus, 496 Main St., Charlestown, Mass., is treasurer; Charles Costello and Dennis McCarthy are directors.

THE NEW JERSEY OIL REFINING Co., Keyport, N. J., has been incorporated with a capital of \$2,500,000 to manufacture refined oil products. The incorporators are Robert Thysem, Earl U. Bartholomew and Arthur L. Turner, Keyport.

THE PUENTE MID-CENTRAL OIL Co., Los Angeles, Cal., has been incorporated with a capital of \$1,000,000 to manufacture petroleum products. The incorporators are G. G. Russell, W. M. Miller and Walter F. Wilkinson. The company is represented by Walter H. Sprague, 811 H. W. Hellman Bldg.

THE G. & R. MFG. Co., Tampa, Fla., has been incorporated with a capital of \$25,000 to manufacture soap products. L. F. Goonrey is president and M. D. Reay secretary and treasurer, both of Tampa.

THE WOVEN LEATHER CORP., Brooklyn, N. Y., has been incorporated with a capital of \$100,000 to manufacture leather products. The incorporators are N. H. Dimon, M. P. Murphy and P. H. Loftus, 80 B'way.

THE ILLINOIS BARITE Co., Main St., Golconda, Ill., has been incorporated with a capital of \$150,000 to operate mineral properties with refining plant. The incorporators are Leslie Wardrop, James Wardrop and G. W. Casey.

THE FREDERICKSEN Co., Saginaw, Mich., has been incorporated with a capital of \$100,000 to manufacture brass, bronze, aluminum and other metal castings. The incorporators are Niels J. Fredericksen, 5740 Lorain Ave., Detroit, Mich.; Alexander M. Lemke and Otto Schrupp, Saginaw.

THE CORTEX CHEMICAL WORKS, Brooklyn, N. Y., has been incorporated with a capital of \$30,000 to manufacture chemicals and chemical byproducts. The incorporators are L. Kuhne, C. Zengerie and D. Spero. The company is represented by B. G. Greller, 299 B'way, New York.

THE JEWELERS' SMELTING Co., INC., Newark, N. J., has been incorporated with a capital of \$100,000 to operate a smelting and refining works for gold and other materials. The incorporators are Marcel Godefroy, Milton A. and Harry C. Helminger. The company is represented by Charles S. Smith, 207 Market St.

THE H. K. T. OIL Co., Los Angeles, Cal., has been incorporated with a capital of \$350,000 to manufacture petroleum products. The incorporators are Roy Lauman, J. A. Rasmussen and Theodore Wittler. The company is represented by Joseph Crail, Union Oil Bldg.

THE TRANSLOID PRODUCTS Co., New York City, has been incorporated with a capital of \$500,000 to manufacture translucent sheeting and other composition products. The incorporators are W. A. Scanlan, L. Meyers and L. Tyler, 51 Chambers St.

THE ORGANIC FERTILIZER Co., Lakeland, Fla., has been incorporated with a capital of \$500,000 to manufacture fertilizer products. The incorporators are W. T. Overstreet, Edwin Spencer, Jr., and W. B. Sewell, Lakeland.

THE ONONDAGA SALT Co., Syracuse, N. Y., has been incorporated with a nominal capital of \$5,000 to manufacture salt products. The incorporators are T. K. Gale, D. W. Peck and T. P. Murray. The company is represented by Daniel A. Pierce, Wieting Bldg.

THE OIL & CHEMICAL CORP., Chicago, Ill., has been incorporated under Delaware laws with a capital of \$335,000 to manufacture chemicals, oils, etc. The incorporators are Abraham Greenspan, A. L. Rittenberg and Lawrence A. Cohen, 11 South La Salle St., Chicago.

THE NATURAL OXIDE CORP., Ford City, Pa., has been incorporated with a capital of \$500,000 to manufacture oxides, purifying materials for gas plants and kindred products. The incorporators are Leroy John, Harry Butler, Ford City; and Guy Ross, Oakmont, Pa.

THE PEERLESS CORK Co., 26 Prospect St., Newark, N. J., has filed notice of organization to manufacture cork products. Charles A. Hauser, 61 Linden St., Irvington, Newark, heads the company.

THE CHARLES B. CHRYSTAL Co., New York City, has been incorporated with a capital of \$200,000 to manufacture waxes, chemicals, etc. The incorporators are C. B. and O. Chrystal, and J. Ormiston. The company is represented by F. J. Knorr, attorney, Albany, N. Y.

THE AUBURN PARK OIL Co., 7222 Green St., Chicago, Ill., has been incorporated with a capital of \$100,000 to manufacture and deal in oil products. The incorporators are Otto Miller, Hugh J. McHugh and W. Gottwold.

THE SOUTH SIDE OIL Co., Salamanca, N. Y., has been incorporated with a capital of \$35,000 to manufacture oil products. The incorporators are R. C. Cooney, T. Conlan and G. A. Adams, Salamanca.

SCHWITTER, CLOVER & STARKWEATHER, INC., Newark, N. J., has been incorporated with a capital of \$125,000 to operate a metal smelting and refining plant. The

incorporators are Martin Schwitter, Charles Clover and George W. Starkweather, 320 Passaic Ave.

THE CLAROTYPE Co., New York City, has been incorporated with a capital of \$100,000 to manufacture type-cleaning fluids and other chemical compounds. The incorporators are L. and E. Banov, A. Henderson and L. Mintz, 19 West 44th St.

Industrial Notes

THE CHEMICAL EQUIPMENT Co. announces the removal of its general offices from 910 Monadnock Bldg. to 2457-59 South Western Ave., Chicago, Ill.

HUGO SCHLATTER has resigned his position as manager of the chemical products division of the Hercules Powder Co. and plans a trip to Europe early in July. While abroad he will visit industrial centers and is prepared to undertake commissions for American manufacturers who desire special investigations and reports on conditions abroad. Mr. Schlatter may be addressed at P.O. Box 26, Wilmington, Del.

THE ELECTRIC HEATING APPARATUS Co. announces the removal of its general offices and factory to 18-34 Nesbitt St., Newark, N. J.

Capital Increases, Etc.

THE SINCLAIR & VALENTINE Co., 611 West 129th St., New York City, manufacturer of lithographing inks, etc., has filed notice of increase in capital from \$400,000 to \$1,600,000.

THE EAGLE LAKE BRICK & TILE WORKS, Eagle Lake, Ill., has filed notice of dissolution under state laws.

THE MAC SIM BAR PAPER Co., Otsego, Mich., has filed notice of increase in capital from \$1,200,000 to \$2,400,000.

THE GOODYEAR RUBBER Co., 787 B'way, New York City, has filed notice of increase in capital from \$500,000 to \$2,615,000.

THE ROOSEVELT DRUG & CHEMICAL Co., 117 Smith St., Perth Amboy, N. J., has been granted a certificate of dissolution under state laws.

THE BARTLES-SWEENEY OIL Co. of ILLINOIS, Peoria, Ill., has filed notice of increase in capital from \$15,000 to \$300,000, at the same time changing its name to the Sweeney Gasoline & Oil Co.

WILLIAM S. GRAY has been appointed receiver for RALPH L. FULLER & Co., 81 Fulton St., New York City, manufacturers of chemicals and paints, in bond of \$50,000. The company's liabilities are said to aggregate \$480,000, with assets in excess of this sum.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY's summer meeting will be held at Canton, Alliance, Sebring and East Liverpool, Ohio, July 25 to 27. Headquarters will be at the Hotel Courtland, Canton, Ohio.

AMERICAN CHEMICAL SOCIETY, THE SOCIETY OF CHEMICAL INDUSTRY and the American Section of the latter society will hold a joint meeting in New York, Sept. 6 to 10.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in Lake Placid, N. Y., Sept. 29 and 30, and Oct. 1.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its fall meeting at Wilkes-Barre, Pa., Sept. 12 to 17.

AMERICAN MINING CONGRESS AND NATIONAL EXPOSITION OF MINES AND MINING EQUIPMENT will hold its twenty-fourth annual convention in the Coliseum, Chicago, Oct. 17 to 22.

AMERICAN SOCIETY FOR STEEL TREATING will hold its third annual convention and exhibition Sept. 19 to 24 at Indianapolis.

THE NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SEVENTH) will be held during the week of Sept. 12 in the Eighth Coast Artillery Armory, New York City.

NEW JERSEY CHEMICAL SOCIETY has discontinued meetings for the summer and will resume them in October.

SOCIETY OF CHEMICAL INDUSTRY (BRITISH) at the invitation of the Montreal section will hold its annual meeting in Montreal and other Canadian cities during the week of Aug. 29, 1921. Details will be printed in this magazine from time to time.

Number 2

Now He's Bossing Dad

DOUBTLESS most of our readers and all of our metallurgical friends are acquainted with the *Iron Age*, so that no introductory remarks are necessary. To those of them who do not see it regularly, however, we take the liberty of reproducing the following copyrighted poem by L. G. FIRTH, of the Firth-Sterling Steel Co., which appeared in an ornamental border on one of its recent front covers:

"THE MAN AT THE FIRE"

There are some who forget what experience means,
(They are generally fellows just out of their 'teens)
And by using pyrometers seem to acquire
A lack of belief in—
 "The man at the fire."

They'll talk of "calescence" and "pearlite," and tell
You the value of "cementite":—(sounds very well!)
And the depth of their learning will make you perspire,
But they don't get *results*, like—
 "The man at the fire."

A pyrometer's good when it's kept in its place,
But sometimes you'll find there's a lie on its face,
And then when the heat's climbing higher and higher,
The man who can *tell*, is—
 "The man at the fire."

Now do not mistake me; I say, by all means
While you're lacking in skill, put your trust in machines;
But if to be really expert you aspire,
Then study, as well, with—
 "The man at the fire."

So when you are learning your job, never heed
Those who tell you that skill is a thing you don't need;
For skill and hard work you will surely require,
If you hope to compete with—
 "The man at the fire."

The question immediately arises: Is this an advertisement, or is it not? On first glance, it certainly appears like editorial matter—no product or material is described or bulletined in it. It contains an idea which might readily be treated in this manner in editorial pages. Nevertheless we hasten to affirm our belief that it is an advertisement, unfortunately not censored.

Assume for the instant, however, that it is matter selected for display by the editors. On this assumption one cannot help but speculate what class of readers this poem would attract. It appears to be addressed to the unseasoned technical student, cautioning him against allowing a pyrometer to remain too long without calibration, of using technical terms beyond everyday parlance (although doctors appear to get rich doing just that), and of neglecting the human element involved in all manufacturing operations. These points should

always be borne in mind, although we would judge that the emphasis in the quotation is rather misplaced. It would be a rather safe bet that for every error due to inaccurate electric pyrometers there exist a dozen due to the "human-eye" pyrometer. As a matter of fact, scientific control devotes most of its energies toward preventing errors by "The Man at the Fire."

But we have been told that the *Iron Age* circulates mostly among executives, superintendents and purchasing agents. The small number of immature students seeing this cover would not warrant its use for them. If the editors deliberately address the big men in the industry in this tone, this outside cover appears as a direct slur on applied science; as a reflection of the attitude which rock-ribbed conservatism has always had toward progress. From a reasonable familiarity with the editorial pages of the *Iron Age* and an acquaintance with the editors themselves we therefore decline to believe that they are responsible for this cover. Even the reading pages of the same issue carry in the place of honor, crowding out such important business information as "The Metal Schedule in the New Tariff Bill," an article not by a man at the fire on "An Occurrence of Nitrogen in Steel." We are therefore forced to the conclusion that a certain steel company is willing to pay a considerable sum to advertise (a) that one of its officials is a poet, (b) that its products are still made in the good old-fashioned way, (c) that its steel is immune from any hardening-room abuse, or (d) that the man at the fire is the best judge of excellence in alloy steel.

Such an appeal for a return to the happy-go-lucky methods of rule of thumb displayed so prominently, even in advertising, cannot pass without protest. No thoughtful man but marvels at the heights of metallurgical perfection—oftentimes yet unimproved—reached purely by cut-and-try methods; by groping in the dark. But he also understands how painfully slow was this progress. Iron has been known since man can remember, yet a lingering two thousand years crawled by between the invention of the first crude blowing bellows and its equipment with a simple flap valve! Civilization progresses with ever-increasing speed, however. It took only a short hundred years to change the blast furnace from a machine producing twenty-five or thirty tons of pig iron a week to as much an *hour*. But are we going to throw away our pyrometers, our microscopes, our equilibrium diagrams, our calescences and cementites because "they don't get *results*, like—the man at the fire"? Is the man at the fire a good yardstick to measure an X-ray spectrometer?

After humbly courting a reluctant muse, we submit the following poem (with our humble apologies to CARL SANDBERG) as a counter-irritant. In order that there may be no doubt in the casual reader's mind about its

status, we hereby certify that it contains the germ of CHEMICAL & METALLURGICAL ENGINEERING'S editorial policy.

"NOW HE'S BOSSING DAD."

Bill Jones, he
Was a treater skilled. He
Knew just why he
Put manure into his quenching tub.
But one day,
Ann, Bill's wife,
Said,
"Bill, you're stuck in the mud.
Bill, Jr., goes to Tech."
So Jr. went
And saw
All manner of strange things
On a blackboard
In a microscope
In books;
Then he came home and got a job in the factory.
* * * * *
Now he's bossing Dad.

Progress in The Dye Industry

AMAZING progress was made in the dye industry during 1920. Notwithstanding that for the last three months of the year the majority of the plants were closed or operated on a greatly reduced scale, the industry had an output, according to the recent report of the Tariff Commission, of 88,000,000 pounds of finished products valued at more than \$95,000,000. This is a tremendous increase over the production during 1919 and is practically double the total pre-war imports. That our consuming industries are now almost entirely independent of foreign dyes is shown by the fact that the imports during 1920 amounted to less than one twenty-fifth of the domestic production.

The production of indigo is an example of real progressive development. Since 1917 our output of this important color has increased from 275,000 pounds to over 18,000,000. The latter figure is at least twice the domestic consumption before the war, and indigo has been able therefore to play an important part in our export trade in dyes and chemicals. This production exceeds that of sulphur black, which has previously been produced in largest quantity.

There is still, however, a noticeable lack of variety among the important vat dyes other than indigo. A considerable portion of the imports during 1920 was of these so-called "specialties," which just before the war were beginning to replace many of the older and less satisfactory colors. Some of these, to be sure, were produced in ample quantity, but many other dyes of this faster type have not yet made their appearance.

One particularly significant fact shown by the commission's report is that more than 90 per cent of the total quantity of dyes was produced by three or more manufacturers. This statement would seem to indicate that monopolistic control of particular products has not as yet made great headway in the domestic industry. Perhaps this will to some extent allay the fears of those members of Congress who have opposed the dye legislation on the ground that it is an attempt "to grant exclusive rights to a recognized monopoly."

The dye industry is to be congratulated on the showing it has made, and it is hoped that with the general resumption of business it will not only continue to expand its output but through research and development will produce a wider range of dyes of newer type and better quality.

Looking Forward To Fall Meetings

BY A HAPPY conjunction of events American chemists will have an unusual opportunity for professional intercourse during the last week of August and the first two weeks of September. The headliner on the bill is the British Society of Chemical Industry, which will hold its fall meeting in Canada, and the supporting features are successively the regular fall meeting of the American Chemical Society and the National Exposition of Chemical Industries in New York. British, Canadian and American chemists will mingle at all these functions, which will afford three weeks of opportunity for renewing old acquaintances, making new ones, and incidentally fortifying that bond of fellowship between English-speaking peoples which we are all convinced will be a large factor in the solution of many world problems.

Chemistry should gain fresh impetus in England, Canada and the United States as a result of the meetings that will be held in Montreal and New York. The science and its application to industry have assumed a position of new importance in England just as they have in this country, and while we are showing our visitors something of the efforts we have made to establish a chemical industry in the United States undoubtedly we can learn many lessons from the problems they have encountered and solved. The Exposition will enable us to show our guests concrete evidence of the progress that chemistry has made on this side of the Atlantic. It should prove not only a source of entertainment to them but also a stimulus toward the edification of chemistry in England. It is not too early to begin to plan for a visit to New York from September 6 to 10, when the American Chemical Society will be in session with the Society of Chemical Industry as visitors, or from September 12 to 17, when the Chemical Exposition will be held in the Eighth Coast Artillery Armory. It will be years before a similar opportunity is again afforded.

A.S.T.M. Unable To Join Federation

IT IS to be regretted that the American Society for Testing Materials finds itself unable to join with the Federated American Engineering Societies. An invitation to become a charter member was issued after the Federation had been organized, and has been carefully considered by the executive board of the A.S.T.M. during the intervening months. Action was finally reported and approved by the recent meeting at Asbury Park.

In view of the society's principal utility—which seems to be a medium whereby divergent views of buyer and seller of materials of engineering construction can be harmonized into acceptable specifications—it might be questioned whether such an organization would have interests identified with commerce rather than with engineering. Acquaintance with the personnel of the committees and active men in the society dispels this notion. Even though powerful organizations like the Steel Corporation and the Pennsylvania Railroad are vitally interested in specifications, they are represented almost exclusively by engineers or engineering chemists. Independent consultants and instructors are also much in evidence, and presidents, vice-presidents and salesmen rather scarce. The

result naturally is to inject a pronouncedly engineering rather than commercial atmosphere into committee meeting and general assembly.

Therefore it was not a surprising event when the American Society for Testing Materials was the first society to join the founders of Engineering Council, and its representatives did their share of the work of launching the Federation. But now, after a year's consideration, the executive committee finds that its budget will not be able to furnish the necessary funds for this new affiliation without serious curtailment of its current activities. In view of the present public temper, it was thought inadvisable to increase the dues, a decision which was sustained by the general meeting, despite a motion to refer the whole matter to a letter ballot of the membership.

Knowing the history of the two bodies, there seems to be no reason to doubt the sincerity of the official resolution indorsing unreservedly the belief that the "objects for which the Federation is organized merit the support of engineering organizations and engineers in general," and the further resolution offered from the floor that the present action was not to be construed to prevent affiliation at a later date, when the financial conditions and prospects of the society warrant the step.

Industrial Menace of Tax-Exempt Securities

WHILE the subject of political economy is admittedly outside the editorial scope of this magazine, the matter of taxation is of such vital import to the chemical and related industries that we may be pardoned for calling attention briefly to the McFadden resolution, H. J. Res. 102, pertaining to tax-exempt securities. Students of taxation have for some time been directing public attention to the menace of the continued issuance of tax-exempt securities by the Government and its political subdivisions. It has been estimated by OTTO H. KAHN that up to January, 1921, such securities have been issued to the value of \$14,425,000,000, of which half represents the debts of states, cities, school districts and other political subdivisions and the remainder the obligations of the Government. Obviously individuals of wealth have accumulated these securities as rapidly as possible to such an extent that they are rapidly freeing themselves of the burden of taxation, which is forced onto those less fortunate. The extent to which tax-exempt securities have been segregated in the hands of the wealthy and the consequent effect on the taxable income of individual taxpayers under the federal income tax may be seen in the fact that taxable income of \$992,972,985 in 1916 decreased to \$731,372,053 in 1917 and to \$392,247,329 in 1918.

The effect of Mr. MCFADDEN'S resolution would be to amend the Constitution in such a manner as to place all forms of investment on an equitable basis of competition and to re-establish equality in the assumption of the tax burden by all the people. The former is of direct interest to the normal progress of industry and the latter is of personal interest to every federal tax payer. As nearly as we can ascertain competent opinion in the matter, legislation to abolish tax-exempt securities is highly desirable and we feel justified in bringing the matter to the attention of our readers with the suggestion that they take legitimate steps to encourage the passage of the McFadden resolution or similar legislation.

Steel Prices And Wages

THE American steel industry is displaying very plainly an anxious desire to play fair with its workmen and its customers. Steel prices have been declining. There having been at least two markets in 1920, the Steel Corporation holding its prices to the Industrial Board schedule of March 21, 1919, while the independents made large advances, the independent market has been declining for almost a twelvemonth, while the Steel Corporation's prices began their decline April 13 of this year. The decline has brought steel prices to a level between 50 and 60 per cent above the pre-war level, according as one takes as basis for comparison the ten years ended with 1913, the five years ended with 1913 or the average of 1913 alone.

The major portion of the steel-consuming trade has not desired that steel prices be cut ruthlessly. In most cases the manufacturing consumers have had stocks of steel or of their manufactures, made from steel, which they desired to liquidate. They wished to sell their goods, rather than buy steel, hence in many cases the steel mills would be rendering their customers a disservice by reducing prices. At the same time it was to the interest of the steel makers not to slash prices, as they would obtain little if any more business by doing so.

Last week the Bethlehem Steel Co., one of the most prominent of the independent producers, formally announced a schedule of price reductions, and the action was followed, formally or otherwise, by other independents, while a couple of days later the Steel Corporation made a formal announcement of the same tenor. To the layman it may have appeared that the steel market had been pegged at a certain point, that a new peg was inserted farther down and that the first peg was forthwith pulled out. That, however, was hardly the case. During the preceding week the open market had really sagged and the new prices were chiefly a formal recognition of prevailing prices.

The steel industry is gradually reducing its wages, and evidently one object of the formal announcement as to prices was to remove the appearance of the steel mills receiving higher prices for their product than they really were receiving.

The Steel Corporation now pays 37 cents an hour for common labor, as do a few of the independents. Others are paying 33 cents and 30 cents, down to 27 and 25 cents, in the case of certain Eastern mills. Contractors in the Central West pay 25 and 30 cents.

The mills are giving the workmen the better end of the bargain. The rate for common labor before the war—as a matter of fact from February 1, 1913, to February 1, 1916—was 19 cents. With steel prices 50 to 60 per cent higher, a corresponding rate would be 30 cents, and that probably will be the final objective, but not until steel prices have further declined.

At the end of 1914 steel prices had practically returned to their historic low level, made in 1897 and 1898, when the wage rate was 13 cents. The mills had absorbed a 50 per cent increase in wages, by making improvements in methods and appliances. They cannot absorb another 50 per cent wage increase, because they have not made corresponding improvements, nor have they anything from which to absorb the great increases in freight rates, but it is plainly the spirit of the industry to pay fair wages and have wages dictate the price of steel rather than allow steel prices to dictate wage rates.

British Chemical Industries

(FROM OUR LONDON CORRESPONDENT)

LONDON, June 17, 1921.

INDUSTRIAL troubles are still with us and prophets have either gone out of business or are utterly discredited. The end does not yet seem in sight either as regards coal or for many other industries in which the pendulum is swinging against the operatives. A state of affairs which, according to quite reasonable predictions on the pre-war basis, should mean the complete and utter ruin of this country has been borne by the general public with an uncanny apathy amounting almost to stoicism and by manufacturers with an uncrushable optimism of the "it might be even worse" variety. The undertone in chemical markets continues good, and in spite of the adverse conditions prices are well maintained.

GAS WORKS OPERATE UNDER DIFFICULTIES DURING THE COAL STOPPAGE

The public during the last two months has relied largely on the gas companies and the flexibility of modern plant is well illustrated by the manner in which all difficulties were overcome. French coal was chiefly used and a certain amount also arrived from Germany and Pittsburgh. On account of the somewhat heavy percentage of ash in the French coal and its smaller yield in residuals, costs in raw materials per "therm" were much greater than for British coal, while the heavy freightage militated against the extended use of American fuel. Sulphur in all cases was lower than for British coal, but in spite of all efforts the various gas companies are faced with heavy losses in operation which could only have been partly avoided by shutting down. Heavy petroleum distillates being now relatively cheap owing to the fall in oil prices, carburetted water gas was extensively used, and this as well as prompt supplies of French coal really saved the situation. The gas works engineers have had an anxious time technically and perhaps the chief lesson learned is that if and when the British coal-mining industry returns to sane conditions, it will hardly have lost any of its market among the gas works.

FUEL RESEARCH BOARD PUBLISHES GAS RETORT STEAMING TESTS

The Glover-West retort was selected as the most suitable for these tests because of the ease with which the temperature can be controlled, and a setting of four retorts was installed during 1919 at the Experimental Station at East Greenwich. Coal from Durham, Yorkshire and Lanarkshire was tested as being of widely different types, and while at first 5 per cent of steam was used as a starting point, it was later on realized that a steamless starting point was necessary. It was common knowledge that steaming would lead to an increased yield of "therms" in the form of soluble gas, but the probable effects of steaming on the other products obtained was not so clear. The tests have shown that steaming also leads to increases in the yields of tar and ammonia at some slight sacrifice in the quantity and perhaps quality of the coke. It is concluded that provisionally 20 per cent of steam represents the economic limit for the time being subject to definite determination for different coals; the total gains obtained at an expense of 10 therms in the form of steam and fuel are stated to

be 33 therms of gas, 34 lb. of tar and 6 lb. of sulphate of ammonia, all reckoned per ton of coal.

TRADERS HANDICAPPED IN GERMAN TRADE

The debate on the safeguarding of industries bill ultimately degenerated into a free trade versus tariff reform controversy and no suggestions of a practical kind were made as an alternative to the bill. As in the case of other bills of this type, the House of Lords is far more likely to bring forward constructive criticism and sound arguments for and against its various provisions. While Parliament is dabbling with a half-hearted scheme, real attention has been focused upon Mr. McKenna's views embodied in an address on international debts. It is argued that in order to enable Germany to meet her final liability of close on 1,600 millions a year her exports must amount to not less than 4,800 million dollars. Obviously German foreign trade could not be expanded to this extent unless wages are kept extremely low with a corresponding rigid cutting down of the standard of living. Attention is drawn to the fact that Great Britain's international trade would be gravely impaired if Germany is able to meet her obligations, and this could only be partly avoided by reparations exports of coal, timber, potash, sugar and the like, this being equivalent to a handicap on German industry. Otherwise the reparations are shown to be really a bonus in favor of Germany, and shipping is given as an example.

Meanwhile importation of goods from Germany can be carried on only under great difficulties and with considerable delay, owing to the absence of official German announcements in regard to the refund of the 26 per cent reparations and export duty. The chief free imports at the moment are patents and processes of all kinds, which have been developed in ex-enemy countries during the war and which are being freely absorbed by British firms in the traditional manner.

NEW PROCESSES AND GENERAL NOTES

Considerable attention has been attracted to Mr. Hayhurst's new method of electrical heating and drying, in which the liquid is at no time at a higher temperature than the highest to which the liquid is to be raised. Further details will shortly be available, but it may be stated that the current in the one case is passed direct through the liquid and in the case of driers induced currents and hysteresis effects are utilized. During the war, electrical heating was developed in countries such as Italy, where coal was obtainable only at prohibitive prices, but in those cases electrodes were usually used. The present process from all accounts is likely to have extended application and of course particularly in localities where electrical energy is obtainable at low rates. Another interesting process is Calvert's for the synthetic direct production of alcohol from water gas and producer gas by catalysis. It is stated that ethyl alcohol of 99.2 per cent purity had been obtained from ordinary water gas with a yield of 90 per cent.

The announcement of the election of Dr. Ruttan to the presidency of the Society of Chemical Industry was unaccountably delayed at this end, although it was common property through American and Canadian sources. One of the new vice-presidents, C. S. Garland, is managing director of Lighting Industries, Ltd., and is one of the delegates to the forthcoming annual meeting in Canada.

Studies in Colorado Shale Oils

Results of Investigations on Shale Oils and Their Fractions, With Special Reference to Their Content of Sulphur and Nitrogen and to the Increased Saturation by Cracking

By ARTHUR J. FRANKS

IN A previous preliminary paper¹ the author presented some fundamental data on a number of Colorado shale oils which indicated clearly the similarity between the different products from the same type of oil shale. It was also shown that the heavy fractions of these shale oils are rather easily cracked on distillation at atmospheric pressure, the resulting distillates having a much higher saturation than the original oil. The only plausible explanation suggested for this phenomenon was that the increase in saturation might be due to the formation of new saturated compounds from some of the heavy unsaturated material. The present communication represents the results of further investigation on some of the same oils and their fractions, and deals mainly with the distribution of sulphur and nitrogen.

The unstable, unsaturated substances in Colorado shale oils are very complex and it would be a hopeless task to attempt to isolate and identify even a few of them without first studying some of the prominent general properties of the fractions in which they occur. The work done thus far in this direction only raises further questions instead of answering previous ones. Therefore it was thought advisable to proceed further with the preliminary investigation of the same oils before undertaking any general study of different types of oils or of the specific compounds in any one. It was hoped that simple distillations and analyses of the fractions for sulphur and nitrogen, in connection with the results obtained for saturation, specific gravity and temperature, would reveal, or at least indicate, some of these fundamental properties, as well as shed a little light on the phenomenon of increased saturation by cracking. Obviously, then, the purpose which underlies these preliminary studies is to discover the hidden road that leads to the main highway of ultimate investigation.

PRESENCE OF SULPHUR COMPOUNDS IN SHALE OILS

The distribution of sulphur, aside from its importance in connection with refining problems, may yield valuable information on the possible composition and properties of some of the compounds present in Colorado shale oils. In the dry distillation of the heavy fractions of these oils a strong odor of hydrogen sulphide is always noted, indicating decomposition of sulphur compounds. Since all of the heavy compounds of sulphur decompose more or less on distillation, this would be expected, and does not give any indication of the possible forms in which the element might occur. Casual examination and tests fail to give much additional information, except to indicate that the usual compounds do not seem to be present in quantity. The

only sulphur compounds that have ever been found in oils and the characteristics of which are known fall into the following classes: (a) Hydrogen sulphide; (b) carbon bisulphide;² (c) alkyl sulphides,³ or thioethers; (d) thiophenes;⁴ (e) thiophanes,⁵ and (f) mercaptans.⁶ Most of the sulphur in the oils studied does not seem to be present in any of these forms, but rather in forms suggesting an asphaltic nature and a very complex structure. Whatever their real nature may be, a knowledge of the amount of sulphur present will be of value, especially as a basis for other researches.

The accurate determination of small amounts of sulphur in oils presents many difficulties, especially when a great number of analyses are to be made. While sufficiently precise for most practical purposes, the usual technical methods give results which are not at all exact, even though considerable care is used in their application. Some of them contain such a number of sources of possible error that correct values obtain only by chance. Others are either long and awkward or require the use of such expensive apparatus that a large number of determinations becomes prohibitive. Since it is beyond the scope of this paper to discuss the relative merits and defects of different methods for determining sulphur, only the two which were actually tried will be given consideration.

It was realized early in the investigation that the only methods which could be utilized in making many accurate analyses on shale oils were the modified nitric acid method of Waters⁷ and the sodium peroxide fusion method devised by Edinger⁸ and modified by Parr.⁹ Waters' method was tried first, and the sulphur in the crude oils¹⁰ was obtained thereby. A brief outline of the procedure is not out of place.

NITRIC ACID METHOD FOR THE DETERMINATION OF SULPHUR IN SHALE OILS

Two grams of oil was weighed into a 75-c.c. casserole and 7 c.c. of concentrated nitric acid (previously saturated with bromine) was immediately added and the casserole covered with a watch glass. After all violent action had ceased the mixture was heated on a steam bath for about three hours, the crucible being gently shaken from time to time to insure complete

attack by the acid. The casserole was then cooled and about 8 to 10 g. of dry, pure sodium carbonate was cautiously added and the mass stirred into a paste, a little water being added if necessary. The mixture was then dried thoroughly on a steam bath and carefully ignited to a white melt, which was later dissolved in water and the sulphur precipitated by barium chloride in the usual manner. Two blanks were run on each new lot of reagents, which are never pure.

The greatest difficulty encountered was that of too rapid combustion of the organic material when the mixture was fused, even with application of extreme care by the operator. The enormous heat developed often caused the volatilization of some of the salts, and in some cases considerable loss occurred by sputtering. However, careful duplicate determinations often checked fairly well, so that the reliability of the method was not questioned, in spite of the fact that results were occasionally obtained which varied widely. This was thought to be due to carelessness. Hence the publication of the best data for the sulphur in some of the crude oils was thought to be justified.

Recently, however, a large number of determinations has shown surprising vacillations in the amount of sulphur present in the different fractions. Since previous analyses gave no cause for anticipating such results the reliability of the method was finally suspected. Many redeterminations on the same oils proved that our suspicions were correct and that the results given are in error. The author does not attempt to advance any excuse for this unfortunate blunder, but takes the blame upon himself entirely. It is hoped that the present efforts will partly atone for this past mistake, as they bring to light the main failures in the method already mentioned, as well as those in the sodium peroxide fusion method which was eventually adopted. Since a complete discourse on this subject would be too long to be included here, only the main points will be considered briefly, a fuller and more detailed discussion being reserved for a later paper.

A careful study of the nitric acid method showed that the main defects were due to the use of too large a sample of oil (2 g.) and the use of an insufficient amount of sodium carbonate. When the sample of oil was reduced to 1 g., the volume of nitric acid (and bromine) to 5 c.c., and the weight of sodium carbonate increased to 12 g., concordant results were obtained, although they were still a trifle lower than those obtained by the fusion method. It has the additional disadvantage of being longer. In case Parr bombs are not available, however, the Waters method is to be recommended.

SODIUM PEROXIDE FUSION METHOD FOR THE DETERMINATION OF SULPHUR IN SHALE OILS

The peroxide fusion method does not give exact results unless a number of precautions are closely observed. Investigation has shown that with a good balance and extreme care it is possible to check determinations to within 1 per cent of the total sulphur present when this amounts to between 0.5 and 1.0 per cent of the oil. When more sulphur is present, the differences are, of course, proportionately smaller. Thus duplicate determinations on an oil containing 0.75 per cent of sulphur should agree as closely as 0.747 and 0.755. Frequently results have been obtained which check as closely as 0.748 and 0.752 per cent. These represent very accurate determinations when it is con-

sidered that those obtained by the usual methods seldom agree as closely as 0.74 and 0.76, which gives a difference of about 3 per cent of the total sulphur present. A brief description of the procedure eventually adopted is given in the following paragraph:

One measure of sodium peroxide, 1 g. of powdered potassium chlorate and 0.2 g. of benzoic acid are placed in a Parr bomb and well mixed by shaking. About 0.5 g. of the uniform sample is weighed into this mixture by means of a medicine dropper and a small weighing bottle. The whole mass is then thoroughly mixed over a piece of glazed paper with a thin glass rod, any solids adhering to the rod or falling upon the paper being subsequently returned to the bomb. After ignition in the usual manner the fusion is carefully dissolved in about 50 c.c. of water, the bomb thoroughly washed with water, the inside being finally rinsed with about 1 c.c. of concentrated HCl and a little more water, and the solution made acid with concentrated HCl. About 5 c.c. of saturated bromine water is then added to oxidize all the sulphur to sulphuric acid and the iron to the ferric condition. Ammonia is added until the liquid is alkaline and the solution brought to a vigorous boil to coagulate the ferric hydroxide and expel the excess ammonia. The former is then filtered off, a small wad of absorbent cotton being placed in the bottom of the filter to hasten the operation and facilitate washing. Four thorough washings with hot water are sufficient. The solution is acidified with 1 c.c. of concentrated HCl, made up to 225 c.c., brought

to a boil and 5 c.c. of 10 per cent barium chloride solution is added slowly from a pipette. The boiling is continued until the precipitate is well formed, which sometimes requires as much as twenty minutes. About 200 c.c. of liquid will remain. After standing over night the precipitate is filtered through a close 7-cm. filter paper (Munktell's No. 00 is preferred) and is carefully washed until free from chlorides. Ignition is made in a very small (about No. 000) porcelain crucible. The final precipitate will be pure and white. The sulphur is calculated from the barium sulphate weighed. A blank is run for each new lot of reagents and the gross result corrected accordingly.

The corrected results for the sulphur in the crude oils, together with those for the sulphur in the 10 per cent fractions, are given in Table I. The distribution of the sulphur is represented graphically by the curves in Fig. 1. The sulphur was not determined in the fractions of all the oils, because the results obtained are so similar that further analyses would be of no particular value. The corrected value for the sulphur in oil No. 1 is not given in the table, but is 0.72 per cent. A number of duplicate determinations are given for those fractions of oil No. 9 which furnish the turning points in the sulphur curve. The agreement is very

good. These results alone are indubitably not a sufficient basis for any conclusive generalizations; nor were they so intended. Yet, they serve to establish a few facts and bring forth a number of important questions.

A study of the curves reveals a striking regularity in the apportionment of the sulphur among the various fractions. Obviously the 20 to 30 per cent cut contains the greatest percentage in every case except that of oil No. 7, which is not a representative crude oil, but a fractional condensate consisting of a mixture of light and heavy oils. It seems rather surprising to find such relatively small differences in the amounts of sulphur present in the different fractions. The very light oils

FIG. 1. SULPHUR CONTENTS OF SHALE OILS AND THEIR FRACTIONS

apparently contain the least sulphur, while there is but little variation between the percentages found in the middle cuts. It is very important to observe the decrease in the sulphur in the heavy oils, which is undoubtedly caused by cracking. This is evident if the sulphur curves are studied in connection with those for saturation, specific gravity and temperature." Whenever the temperature ceases to rise, then falls, the specific gravity of the distillate at the same time decreasing and its saturation increasing (these phenomena being the criteria for cracking), a lowering is to be observed in the percentage of sulphur; and this becomes more and more pronounced as the cracking progresses. The lowering is not so great as might be expected, however, and there does not seem to be any quantitative relationship between this and other changes in the oils.

ACTUAL LOSS OF SULPHUR IN THE FRACTIONATION OF CRUDE SHALE OILS

The strong odor of hydrogen sulphide noted during the cracking of the heavy oils was an early indication of a loss of sulphur through a decomposition of at least a part of the complex sulphur compounds. That there is a considerable loss is unquestionable, as calculations from the analyses show. In order to compute the actual loss correctly, the total sulphur in the distillate must be subtracted from that in the crude oil. The difference between the average of the sulphur in the fractions and the sulphur in the crude is not the true loss at all. Since the falseness of the latter process of computation is not always obvious, the correct method is here given. The total sulphur in the distillate is the sum of 100 times the products of volume, specific gravity and percentage of sulphur in each fraction. The total sulphur in the crude oil is 100 times the product of volume, specific gravity and percentage of sulphur. The difference is, of course, the actual loss in weight

of sulphur. If the sulphur in the distillate of oil No. 9 is calculated in this manner, it is found to be 2.47 g., while that in the crude oil amounts to 3.50 g. Hence the loss of sulphur is 1.03 g., or 29.3 per cent of the total amount present.

The total loss in weight of oil by the distillation is 21.3 per cent, of which 11.0 per cent is coke. Now, if all the material that decomposed contained sulphur, it would mean that 8 per cent of all the sulphur (or 37.5 per cent of the decomposed material) failed to recombine to oil, but either escaped as hydrogen sulphide or remained in the coke. Such losses as these would account for the slight difference between the sulphur in crude oil No. 3 and that in the distillate No. 3a, the high percentage of sulphur in the light oils, and suggests that it will be impossible to eliminate much of the sulphur by cracking distillations. The fact that the cracking was always accompanied by a loss of sulphur by no means proves that the sulphur compounds only suffered decomposition, in spite of the fact that the phenomena always seem to occur together and at about the same temperature in every case. The evidence merely points in that direction. There is no doubt, however, that practically all the material which cracked was unsaturated (regardless of whether or not it was composed entirely of sulphur compounds) and that most of the saturated compounds were formed from the decomposition of this material.

COMPOSITION OF SULPHUR COMPOUNDS IN SHALE OILS

The sulphur curves of shale oils are significant in connection with the composition of the sulphur compounds present. The fact that the percentage of sulphur in the middle oils tends to be constant indicates a series of isomers. The pronounced deflection of the first part of all the curves signifies the presence in the light oils of a different series of sulphur compounds from those found in the heavier fractions. The cracking of the heavy oils obscures the true distribution of the sulphur therein, but the writer is of the opinion that there would have been a regular decrease in the sulphur in these oils had the cracking been prevented, in which case the curves would have approached straight lines. This would indicate a third series of sulphur compounds—a homologous series—in which each individual member contained the same number of sulphur atoms. Still other series might, of course, occur in such proportions as to give the same apportionment of the sulphur as here observed. This is quite probable. Much more work will have to be done, however, before any of these suggestions can be established as facts. They are mentioned at present only for the purpose of pointing out the course of future investigations, and to stimulate further research.

PRESENCE OF NITROGEN COMPOUNDS IN SHALE OILS

It is a well-known fact that the products from the carbonization of most bituminous materials contain nitrogenous compounds, and researches on different shale oils have shown that they also contain such substances. Investigators have already isolated and identified a number of heterocyclic nitrogen compounds from Scotch shale oils and some have been detected in Green River oils. The most exhaustive research has, however, been done on petroleum.

The possible forms in which the nitrogen might occur in Colorado shale oils are numerous, but the most im-

portant may be classed under the following heads: (a) Pyridines; (b) pyrrols; (c) quinolines; (d) amines, and (e) very complex substances similar in their nature to asphalt. Preliminary tests seem to indicate the presence of all of these forms.

Williams¹² has long ago isolated and identified pyrrol, pyridine, methyl and dimethyl pyridines, and parvoline in a crude naphtha from a Dorsetshire shale oil. Morrell and Egloff¹³ have reported qualitative evidence of pyridine and its homologues in Green River oils. Beilby¹⁴ has done considerable work on the nitrogen in oils from Scotch shales, but he made no attempt to isolate or identify the individual compounds. In spite of the great importance of such knowledge, relatively little has been published and the literature is very meager.

Before making any attempt to determine the classes of compounds present in the oils studied or to identify the individual members of any series it was thought advisable to investigate first the distribution of the nitrogen among the different fractions, since this would yield preliminary information of importance. Three typical oils were chosen for this work—Nos. 5, 6 and 9. The results obtained were so characteristic that further analyses were deemed unnecessary. The nitrogen was determined in all cases by a slight modification of the Kjeldahl-Gunning method. A brief description will indicate its simplicity.

One gram of oil was weighed from a small bottle into a 500-c.c. Kjeldahl flask and immediately treated with 20 c.c. of concentrated sulphuric acid. Ten grams of

tion of sodium hydroxide run into the flask through the funnel until the solution turned to a deep blue, and an excess of about 10 c.c. of the alkali added. The ammonia was cautiously distilled into 50 c.c. of N/20 sulphuric acid into which the condenser tube dipped from the time the alkali was first introduced until water began to condense. The level of the acid was then lowered until it barely touched the tube of the condenser. When about 75 to 100 c.c. of water had distilled over, the distillation was discontinued, the condenser tube rinsed with water, and the excess acid titrated with N/20 sodium hydroxide solution, using a few drops of cochineal for an indicator. The end-point was always compared with that obtained by a fresh titration of equal volumes of the standard acid and alkali in order to eliminate possible error in judging when the proper color was reached. Each c.c. of sulphuric acid neutralized by the ammonia represents 0.0700 per cent of nitrogen in the oil. Blanks should always be run with each lot of reagents and the gross result corrected if any ammonia is found, which is seldom the case. The pipette (or burette) from which the standard acid is measured should, of course, be calibrated against the burette from which the alkali is measured.

The copper sulphate was used to accelerate the decomposition of the oil and to serve as an indicator in the addition of the strong alkali. Phenolphthalein could not be used for the latter purpose because it seemed to induce troublesome foaming during the distillation.

5.....	1.674	1.365	1.344
6.....	1.659	1.404	1.305
7.....	1.540	1.351	1.285
8.....	1.654	1.374	1.316
9.....	1.685	1.883	1.470

The use of copper sulphate permits the saving of about one hour in the decomposition of the oil, about three and one-half hours being required when it is absent. The alkali was introduced in the manner described, because slight losses of ammonia were sometimes obtained during neutralization of the solution in the usual way. The loss of ammonia could, of course, be prevented by greater dilution of the acid and the use of less concentrated alkali; but this would mean that the liquid would have to be transferred to a larger flask before distillation and that a greater amount of water would have to be distilled over to insure complete expulsion of the ammonia. This causes an unnecessary waste of time, especially when a great number of determinations are to be made.

No difficulties were encountered with this method and duplicate determinations checked very closely. Agreement to within one or two thousandths of one per cent are quite common and the difference never exceeds one hundredth of one per cent when analyses are carefully made. The results obtained for the crude oils and their 10 per cent fractions are given in Table II. The distribution of the nitrogen is represented graphically by the curves in Fig. 2.

The amount of nitrogen in these oils is comparatively large and exceeds that found in most petroleum, with

potassium acid sulphate and a small crystal (about 0.2 g.) of copper sulphate were then added and the mixture digested until a clear solution was obtained. This required about two and one-half hours. When completely cooled the contents of the flask were diluted with cold water to about 200 c.c., again cooled, a few glass beads introduced, and a small dropping funnel and a Kjeldahl connector were placed in the flask through holes in a tightly fitting rubber stopper. Connection was made with a water-cooled condenser, a strong solu-

the exception of some from California, Japan and Algeria.¹⁵ Analyses of the fractions show that most of the nitrogen lies in the oils boiling above 225 deg. C., and that the amount tends to increase as the boiling point rises. A comparison of the nitrogen curves reveals a number of irregularities, but they all have the same general shape, which would be expected from the fact that the oils are very similar in other respects.

LOSS OF NITROGEN IN THE FRACTIONATION OF CRUDE SHALE OILS

As the curves (Fig. 2) indicate, the distribution of nitrogen in the oils is very much disturbed by the cracking, which causes a great loss in the total amount of nitrogen recovered in the distillates, the losses being proportional to the extent of the decomposition, as the results and calculations therefrom show. If this loss is computed in the same manner as that for sulphur, it will be found to be 41.2 per cent in the case of oil No. 9, 43.9 per cent for oil No. 6, and 35.9 per cent for oil No. 5. Hence the total percentage loss of nitrogen greatly exceeds that for sulphur under the same conditions. This might be explained in one of two ways: Either this nitrogen and sulphur are present in a series of compounds that decompose during the cracking in such a manner that most of the sulphur later recombines while the greater part of the nitrogen fails to do so, or they are present in separate classes of compounds, those containing the nitrogen being the more unstable. The first hypothesis seems by far the more plausible when the relative chemical reactivities of sulphur and nitrogen are considered and because it is a general rule that a loss in one is always accompanied by a loss in the other. The high percentage of nitrogen in the heavy fractions is evidence of the presence of one or more other classes of nitrogenous compounds which are quite stable. The data are, of course, too meager to permit the deduction of any more definite conclusions as to the possible character of the different kinds of compounds.

CONFIRMATION OF THE HYPOTHESIS THAT UNSATURATED COMPOUNDS ARE CHANGED BY CRACKING INTO SATURATED COMPOUNDS

The simultaneous loss of nitrogen and sulphur and gain in saturation forms interesting evidence in support of the hypothesis that unsaturated, unstable material is the source of the saturated compounds produced by cracking of the heavy fractions of Colorado and similar shale oils. That this unsaturated material is made up of a series of unstable compounds of high molecular weight and rich in nitrogen and sulphur (and perhaps oxygen), as the results suggest, seems very plausible. In spite of the strangeness of the phenomenon, it would not be difficult to conceive how, under suitable conditions, it would be possible for the molecules of such unstable substances to disintegrate completely and for the atoms or groups to recombine immediately to more stable series of compounds, such as paraffines, aromatics, alicyclics, olefines and their sulphur and nitrogen derivatives. It would certainly be unlikely, if not impossible, for the resulting products to be as unstable as the original material or less so. The results obtained are, therefore, not contrary to theory, but might almost be expected. An enormous amount of work will have to be done, however, before the suggested hypothesis can be conclusively proved.

¹⁵Engler-Höfer, "Das Erdöl," vol. I, 1913.

SUMMARY

The usual technical methods for determining sulphur in oils are found to be inexact. A slight modification of Parr's method gave accurate results and was used to determine the distribution of sulphur in five of the oils previously studied. The apportionment of the sulphur is quite uniform for all the oils that were investigated, and is such that there are comparatively only slight differences between the amounts present in the various 10 per cent fractions, the percentage being greater in the 20 to 30 per cent cut and tending to remain constant in the middle oils. The sulphur is less in the light and heavy oils, the amount being reduced in the latter by cracking, showing that at least part of the compounds which decompose contain sulphur. The total loss of sulphur during the distillation was about one-third of the amount present in the crude oil. In spite of this, the distillate contains about the same percentage as the original oil. The distribution of the sulphur as represented by the curves suggests the presence of at least three different series of sulphur compounds, two of which seem to be quite stable. The simultaneous loss of sulphur and gain in saturation by cracking indicate that the unsaturated material which is the source of the new saturated compounds contains sulphur.

Colorado shale oils and their fractions contain much nitrogen, which seems to be present as basic compounds, and complex, unstable, unsaturated substances of high specific gravity and molecular weight. The distribution of nitrogen is similar for each of the three oils studied, the heavier fractions containing by far the larger amounts. Cracking of the latter during distillation effects a great loss of nitrogen and masks its true distribution. The total loss observed was about 40 per cent of the nitrogen occurring in the crude oil, showing that one of the classes of nitrogenous substances is very unstable.

The simultaneous loss of nitrogen and sulphur and increase in saturation by cracking suggests the hypothesis that the saturated oils thus formed are produced from unsaturated compounds containing sulphur and nitrogen, which are easily decomposed under the conditions that obtain during a destructive distillation, yielding oils of a more stable and saturated nature. Work is now being done on the changes wrought by successive distillations of shale oils. The results should yield valuable evidence in support of this hypothesis.

ACKNOWLEDGMENT

The author takes this opportunity to express his indebtedness to C. P. Hackett, who helped to work out the method for determining nitrogen and who made the analyses, and to J. P. Bacca, who aided in developing the method for determining sulphur and made the determinations. The writer is also indebted to Prof. A. H. Low for his valuable criticisms and suggestions in the preparation of this paper.

Production of Alcohol in Poland

This year's production of alcohol in Poland, according to the *Kurjer Polski*, a newspaper of Warsaw, will be about 40,000,000 liters, of which 30,000,000 liters will be exportable. Last year's alcohol production was only 10,000,000 liters (1 liter = 0.264 gal.).

Constitution of Gas Atmospheres in Aluminum-Alloy Melting Furnaces

Tabulated Analyses of Atmospheres of Various Types of Aluminum Furnaces, Sampled at Short Intervals During Operation, Furnishing Data Necessary for a Study of Dross and Metal Losses Due to Furnace Operation

By ROBERT J. ANDERSON AND J. H. CAPPS

AS INDICATED in a previous contribution,¹ "Gases in Aluminum Furnaces and Their Analysis," the Bureau of Mines set out to determine by actual analysis the constitution of the gas atmospheres in industrial melting furnaces used for light aluminum alloys, under foundry operating conditions. A portable gas-sampling apparatus was devised, and a large number of samples taken and analyzed, the results of which are given below.

STATIONARY, OPEN, IRON-POT FURNACE

Gas samples were taken from the atmosphere above the metal in a stationary, oil-fired, iron-pot furnace, run without a cover, such as sketched in Fig. 1. The oil was injected by air under pressure, and steam was not employed for oil atomization in any of the furnaces which were sampled. The furnace was one of several units run as a battery in a bank, the waste gases from the combustion discharging into the air at one end of the bank. In furnaces of this type the iron pot is heated over its exterior surface, and there is practically

FIG. 1. CROSS-SECTION OF STATIONARY, OPEN, IRON-POT FURNACE

no opportunity for the products of combustion to come into contact with the metal during melting. The sampling tube was supported on a suitable stand, and the intake end was hung within 1 in. of the bath surface at about the center. The melting charge consisted of aluminum pig plus 50:50 copper-aluminum alloy, No. 12 alloy pig, and No. 12 alloy foundry scrap. There was

doubtless, no contaminating material in the charge which could have given rise to gases on heating.

As might be expected, the gas in contact with the surface of the liquid metal in an open iron-pot furnace would consist of practically unaltered air. Normally, however, owing to draughts or leakage from the combustion space, the gas contains either a small percentage of unburned hydrocarbons (from 0.0 to 0.4 per cent) or their combustion products (H_2 from 0.0 to 0.2; CO_2 from 0.0 to 0.2) or both, in addition to oxygen and nitrogen. Methane was tested for and not found. Since the gas in contact with the liquid metal in a furnace of this type is practically unaltered air, it is evident that dross formation is a direct function of the temperature. The higher the melting temperature the greater the loss by oxidation and nitridation.

STATIONARY, CLOSED, IRON-POT FURNACE

A number of gas samples were taken from the atmosphere above the metal in a stationary, gas-fired, iron-pot furnace, run with a dome-shaped cast-iron cover (Fig. 2). Natural gas was the fuel. The furnace was operated as a single unit, the waste products from the combustion discharging up a small stack connected to the side of the furnace wall. As in furnaces of the foregoing type, the iron pot is heated over its exterior surface, and there should be but little opportunity for the products of combustion to come into contact with the metal during melting. The furnace charge consists of No. 12 alloy scrap (castings, gates, and risers), 50:50 copper-aluminum alloy, and baled aluminum clippings made up so as to give a final alloy of approximately No. 12 composition.

Contrary to what might have been expected, the furnace atmosphere contained quite large percentages of carbon dioxide, and the oxygen and nitrogen contents were rather variable. The burning of oil on the clippings might be expected to show momentarily the presence of considerable carbon dioxide, but this constituent should not be expected to persist during the course of a melting period. The oxygen content of the atmosphere was increased when the cover was opened for charging metal. The high percentage of carbon dioxide may be due to burning out of the carbon in the cast-iron pot or cover since the oxygen is decreased and the nitrogen increased as compared with the percentage of these constituents in air. There may, of course, be some leakage of the products of combustion into the space above the metal which would account for the carbon dioxide content of the atmosphere. Omitting the figures obtained for samples taken after the cover was open, the range of composition for carbon dioxide, nitrogen

¹Published by permission of the Director, Bureau of Mines.

²See CHEM. & MET. ENG., vol. 24, No. 23, June 8, 1921, p. 1019.

and oxygen was as follows: 7.2 to 9.8 per cent carbon dioxide, 84.7 to 86.6 per cent nitrogen, and 3.5 to 8.1 per cent oxygen. Fractional percentages of carbon monoxide, hydrogen and unsaturated hydrocarbons were found once. The atmosphere of this furnace may be considered to be oxidizing, and both oxidation and nitridation of the metal will take place on melting.

STATIONARY, CRUCIBLE FURNACE

Gas samples were taken from the atmosphere in the interior of the crucible in a stationary, gas-fired, crucible furnace run without a cover. Natural gas was the fuel. In this furnace, somewhat as shown in Fig. 3, the crucible was simply set in a round iron shell lined with firebrick, and the crucible was heated over its exterior surface by the combustion of the fuel. The waste gases were discharged through a large hole in the furnace cover. No cover was used on the crucible. In a furnace of this type there is ample opportunity for the products of combustion to come into contact with the metal during melting, since they are discharged with a rotating motion through the top of the furnace. The burner was set so that the flames were projected tangentially and with a rotating and upward motion around the crucible.

The sampling tube was admitted to the atmosphere in the crucible above the liquid metal through the large hole in the top of the furnace and the intake end was held at a point in the center of the crucible space about 1 in. from the surface of the alloy. Analyses of a number of samples from this furnace are given in Table I. The charge contained about 86.0 per cent aluminum,

FIG. 3. SECTIONAL PERSPECTIVE OF STATIONARY CRUCIBLE FURNACE

7.0 per cent copper and 7.0 per cent tin (made up by adding tin to No. 12 alloy pig).

As might be expected, the gas in contact with the surface of the liquid metal in a furnace of this type depends intimately upon the fuel used and the operating details (air supply, etc.). The products of combustion are passing over the metal surface at a fairly rapid rate during melting. As will be noted from Table I, the gas

in contact with the liquid metal contained large amounts of nitrogen. It cannot be considered as oxidizing on the basis of the oxygen content of the gases. The variations in carbon dioxide, carbon monoxide, hydrogen and methane are traceable to variations in the air supply and in the speed of the combustion. It is entirely likely that variations in the constitution of the furnace atmosphere as large as those indicated in the table would be obtained by sampling different parts of the combustion space. Hence the analyses as given are useful only in so far as they indicate the variations in the composition of the atmosphere.

STATIONARY, SEMI-PIT, CRUCIBLE FURNACE

Gas samples were taken from the atmosphere in the interior of the crucible in a stationary, oil-fired, semi-pit, crucible furnace, run without a cover. Fuel oil of unknown composition was used. In this furnace the crucible for melting the alloy was set in a cylindrical iron shell lined with firebrick. The lower half of the shell was set down in a pit. The crucible was heated over its exterior surface by the combustion of the fuel. The waste gases were discharged through a large hole in the furnace cover. No cover was used on the crucible. In a furnace of this type there is also ample opportunity for the products of combustion to come into contact with the metal. The intake end of the sampling tube was held at a point in the center of the crucible space about 1 in. from the surface of the alloy. Analyses of a number of samples from this furnace are given in Table II. No. 12 alloy was melted, and the charge was made up of No. 12 foundry scrap, aluminum pig and 50:50 copper-aluminum alloy.

In the installation under discussion the gas in contact with the liquid alloy during melting was of fairly uniform composition. As will be noticed from Table II, the gas consisted largely of nitrogen and carbon dioxide, with smaller amounts of oxygen. No carbon monoxide or methane was found, and only 0.1 per cent of hydrogen and unsaturated hydrocarbons was detected in one of the samples. Both oxidation and nitridation of the metal would occur in the atmosphere of this furnace.

TILTING, CRUCIBLE FURNACE

Gas samples were taken from the atmosphere in the interior of the crucible in a tilting, crucible furnace of a special design using a good grade of metallurgical coke. In this furnace the crucible for melting the alloy was supported in the furnace shell and heated by the combustion of coke on a grate beneath. The waste gases passed up and around the uncovered crucible and were discharged through a large hole in the furnace cover. Both natural and forced drafts were employed on the

furnace. In this furnace there was ample opportunity for the products of combustion to come into contact with the metal during melting. Analyses of a number of samples from the furnace are given in Table III. No. 12 alloy was melted, and the charge was made up of No. 12 foundry scrap, aluminum pig and 50:50 copper-aluminum alloy.

For natural draft the gas in contact with the liquid alloy during melting was of fairly uniform composition, but the variations were more marked in the case of forced draft. The effect of forced draft upon the constitution of the gas atmosphere is plainly shown. The carbon dioxide content of the gas is higher and the oxygen content much lower, indicating more perfect combustion of the gases before egress from the furnace. When the draft was reduced the carbon dioxide was lowered and the oxygen raised. The high carbon monoxide content of sample taken at 2:17 may be due to several causes—for example, too rapid egress of the unburned gases. Unsaturated hydrocarbons were tested for but not found in any of these samples.

Both oxidation and nitridation of aluminum would occur in a furnace atmosphere of the compositions indicated. It would have been interesting to study the variations in the atmosphere of this furnace over a wide range of draft pressures, but this was impossible.

REVERBERATORY FURNACE

Gas samples were taken from the atmosphere in the interior of an open-flame, oil-fired reverberatory-type furnace. In this furnace the melting was done upon the furnace bottom; fuel was supplied through three burners at one end, and combustion took place in the space between hearth and roof. The products of combustion were discharged into a large stack.

The furnace was approximately 10.0 ft. long by 6.0 ft. wide by 4.0 ft. high inside. There were two large charging doors and a single tapping runner on each side. Considerable air was sucked into the furnace through cracks and holes in the walls and around the doors and burners.

The sampling tube was admitted into the interior of the furnace under the different charging doors, held at various points usually about equidistant from the opposite charging doors and close to the surface of the bath. Analyses of a number of samples taken are given in Table IV. No. 12 alloy was melted, and heavy foundry scrap was used exclusively in the charges.

By reference to the table, it will be seen that the composition of the gas atmosphere in this furnace was very variable, especially as regards carbon dioxide and oxygen. Omitting the figures which are traceable to

definite operating conditions, it is evident that the atmosphere is oxidizing. Taking the last twelve samples, which cover a melting period when the operating conditions were fairly uniform, the composition of the atmosphere ranged about 4.5 per cent CO_2 , 14.5 per cent O_2 and 80.8 per cent N_2 . Both carbon monoxide and methane were found in small percentages in certain of the samples, but hydrogen was detected (0.1 per cent) in only one sample. Both oxidation and nitridation would occur in a furnace atmosphere of this type. Since the gases are passing over the metal at a rapid speed, the gross loss would be a function of the temperature, the composition of the atmosphere and the speed of passage of the gases.

Reverberatory practice is generally to run continuously—cold metal being added periodically to keep pace with the rate of pouring. Since the doors are opened

FIG. 4. END ELEVATION OF OPEN-FLAME STATIONARY FURNACE

from time to time, the atmosphere may be expected to change periodically for this reason if no other. But the atmosphere did not vary widely in different parts of the furnace, as shown by the last set of analyses.

OPEN-FLAME, STATIONARY, CYLINDRICAL FURNACE

Gas samples were taken from the atmosphere in the interior of the open-flame, oil-fired, stationary cylindrical furnace of the Schwartz type sketched in Fig. 4. In this furnace the melting was done upon a cylindrical bottom; the fuel was supplied through two burners on the side, and the combustion took place in the space between the surface of the metal and the cylindrical walls of the furnace. The products of combustion were discharged into the air through a hole in the top of the furnace. The furnace was about 10 ft. long by 5 ft. in diameter inside. There were two charging doors at the side and the end. In this furnace, as in other open-flame furnaces, there was ample opportunity for the products

of combustion to come into intimate contact with the metal.

Owing to the fact that the incandescent gases were constantly in violent motion, it was not necessary to place the sampler very close to the bath. It was admitted through a hole in the end charging door and luted with clay. The end was held at a point about 3 ft. in the furnace from one end and midway between the opposite walls, several inches above the metal surface.

Analyses of a number of samples are given in Table V. No. 12 alloy was melted, the charge consisting of No. 12 alloy pig, aluminum pig plus 50:50 copper-aluminum alloy, and heavy foundry scrap.

The constitution of the gas atmosphere in a closed furnace of this type should remain fairly constant for a given set of operating conditions, and the constituents present in the gases, as shown by the table, vary within

small limits. The atmosphere as found would not be considered as oxidizing unless there is a reaction between carbon dioxide and aluminum at moderate temperatures (700-900 deg. C.).

OPEN-FLAME, TILTING, EGG-SHAPED FURNACE

Gas samples were taken from two different open-flame, oil-fired, tilting, egg-shaped furnaces. In the first furnace (No. 2 Hawley-Schwartz) the melting was done upon the bottom of the furnace; the fuel was supplied through two burners located at one side and near the top which projected the flames down upon the metal. Combustion took place over the metal bath, and the products of combustion were discharged into the air through the open pouring spout on one side of the furnace. This furnace was about 3.5 ft. in diameter. The charging door was at the top. The sampling tube was admitted into the interior of the furnace through a

hole in the charging door and luted in place with clay. The intake end of the tube was held at a point in the approximate center of the interior and several inches above the surface of the bath. Analyses of a number of samples are given in Table VI.

The constitution of the gas atmosphere in a closed furnace of this type should remain fairly constant for a given set of operating conditions. The variations in the percentages of the various constituents as shown in the table are undoubtedly due to burner adjustments.

Methane up to 2.0 per cent was found in some of the samples. The atmosphere is a difficult one to analyze from the melting standpoint, owing to the peculiar relative percentages of the various constituents in certain of the samples. At times it was plainly oxidizing, while at others the oxygen was low and the carbon monoxide quite appreciable. In a few samples both oxygen and carbon monoxide were present.

INDIRECT-ARC, ROCKING, ELECTRIC FURNACE

Gas samples were taken from an indirect-arc, rocking, electric furnace (Detroit type), of 2,000 lb. brass capacity (Fig. 6). The general features of this furnace as used for non-ferrous metal melting are well known and detailed description is not necessary here.² The charge is put in through a door at the side and melted by the heat of the arc from a pair of electrodes centered horizontally in the furnace. Any gases present in the interior of the furnace are in intimate contact with the metal, but the atmosphere is doubtless fairly uniform throughout, since ingress of air or egress of gases does not take place when the furnace is tight.

The sampling tube was projected 15 in. into the furnace through the pouring spout and luted in place with clay. It was not attempted to hold the intake end close to the liquid metal surface.

Analyses of a number of samples are given in Table VII. The furnace was run on No. 12 alloy, made up with aluminum pig plus 50:50 copper-aluminum alloy in most of the heats.

²"A Rocking Electric Brass Furnace," by H. W. Gillett and A. E. Rhoads, CHEM. & MET. ENG., vol. 18, p. 583 (June 1, 1918).

FIG. 6. DETROIT ROCKING FURNACE

The original atmosphere, immediately after charging, should consist of unaltered air. With the arc on and the furnace in operation, the oxygen will combine with the carbon of the electrodes with the formation of carbon dioxide. Then, with the oxygen used up, the carbon dioxide is reduced by the hot carbon with the formation of carbon monoxide. During the greater part of a melting period the furnace atmosphere may be expected to be high in carbon monoxide. Referring to the data given in the table, it will be seen that the carbon monoxide content of the atmosphere was generally quite high. For a short melting period between 11:08 and 12:20 (not included in the table) the range of composition was as follows: 21.0 to 39.3 per cent carbon monoxide, 0.0 to 2.7 per cent CO₂, 50.5 to 72.6 per cent nitrogen, 0.0 to 5.1 per cent oxygen; 0.1 to 3.0 of methane; 0.4 to 7.0 per cent of hydrogen, and 0.0 to 2.1 of cyanogen.

Over a long melting period, as covered by samples taken from 10:54 to 12:23 inclusive, changes in the constitution of the atmosphere were marked. Thus, carbon monoxide and hydrogen generally become less with longer duration of the melt. Carbon monoxide possibly reacts with aluminum, thus:

No analyses were made of the dross obtained on melting aluminum alloys in this furnace, but it should show aluminum oxide, aluminum nitride and aluminum carbide. Cyanogen was smelled throughout, but was not found on analysis. It is due to the direct union of carbon and nitrogen at the temperature of the electric arc. The source of the hydrogen is unknown, although a small part of it may be evolved from the aluminum on melting. Taken by and large, the atmosphere of this furnace after the arc has been on for a short time will be high in carbon monoxide and nitrogen and low in carbon dioxide and oxygen. Such an atmosphere appears to oxidize aluminum; it would, of course, be reducing to copper and zinc.

GRANULAR-RESISTOR ELECTRIC FURNACE

Gas samples were taken from a granular-resistor electric furnace (Baily type) with capacity of 1,500 lb. brass. (Fig. 7.) The general features of this furnace

FIG. 7. BAILY GRANULAR-RESISTOR FURNACE

as used for non-ferrous metal melting are well known.³ The charge is melted upon a bottom by the reflected heat from the granular carbon resistor placed in a circular trough above the hearth. If luted tightly, there should be no ingress of air. The actual atmosphere may vary at different points.

The sampling tube was admitted to the interior of the furnace through the pouring spout, and the intake end was held at a point about 1 in. above the metal surface and in about the center of the furnace. Analyses of a number of samples are given in Table VIII. The furnace was run on No. 12 alloy, the charge con-

further because the temperature is not so high as in an arc furnace, it might be expected that the carbon dioxide would be higher and the carbon monoxide lower in the granular-resistor than in the arc furnace.

The drosses obtained from the indirect-arc and the granular-resistor electric furnaces appear to be entirely different in character. No aluminum carbide is thought to be present in the dross from the latter, and evidently the temperature is not sufficiently high to cause interaction of aluminum and carbon monoxide.

DISCUSSION OF THE RESULTS; TOXICITY OF GASES

In considering the detailed analytical data given in the tables, it is of interest to note that the constitution of the gas atmosphere in a metal-melting furnace may be, and usually is, quite variable during a melting period. During a day's run in a foundry, the gas atmosphere in a furnace may be exceedingly variable. In oil- and gas-fired, open-flame furnaces, the firing conditions vitally affect the constitution. It is extremely speculative to attempt to state why a furnace atmosphere should contain certain percentages of the different constituents at a particular moment, and the authors will not attempt to present a detailed analysis of the data as set forth in the tables. As has been stated previously, the main object of the study was to determine the actual constitution of the gas atmospheres in contact with metal in typical industrial furnaces used for melting light aluminum alloys in foundry practice. The fact that the effects of most of the constituents of the gas atmospheres upon the properties of aluminum and its light alloys are largely unknown makes any discussion of this aspect of the subject speculative.

sisting of No. 12 foundry scrap and aluminum pig plus 50:50 copper-aluminum alloy.

It would be expected that considerable carbon monoxide would be present in this furnace as well as in the Detroit furnace, provided the furnace is tightly closed and the melting period is sufficiently long. Referring to the data given in the table, it will be seen that the carbon dioxide content of the atmosphere was quite high, while the carbon monoxide content was variable. In a similar Baily furnace operating on brass, carbon monoxide up to 20.0 per cent was found, indicating that the reduction of carbon dioxide by carbon was more complete at the higher temperature obtaining. The oxygen content of the furnace was quite low, while hydrogen and methane were ordinarily present in small amounts. Owing to the fact that a large volume of air is contained in the furnace at the time of charging and

Some atmospheres prevailing in the melting furnaces contain carbon monoxide and cyanogen and are extremely toxic. No report of injury due to the inhalation of furnace gases in foundries have come to the attention of the authors, and no analyses of foundry melting-room atmospheres have been made in this investigation. Where the gases are discharged into the outside air through a stack, there is small possibility of contamination of the foundry atmosphere by toxic or non-toxic gases, but where the products of combustion are discharged directly from the furnace into the foundry atmosphere, it appears that a real danger exists. With good ventilation, an atmosphere containing high percentages of CO would be rapidly diluted.

Proper ventilation and suitable means for removing furnace gases to the outside air will probably prevent any serious cases of gas poisoning in melting rooms, but it is evident that even under these conditions, a man working too close may be injured.

Relation of Structure to Free Alkali in Sodium Silicate Solutions*

BY WILLIAM STERICKER†

AMONG chemists there are a great many misconceptions about sodium silicate. The literature is full of contradictions and standard text-books contain many erroneous and misleading statements about it. Failure to specify the composition of the material is often the cause of the contradictions. The ratio of Na_2O to SiO_2 in sodium silicate solutions may vary from 1:1 to 1:4, although in commercial grades the limits extend only from 2:3 to 1:4.

One question frequently asked is, "Do not sodium silicate solutions contain large quantities of free alkali?" The general opinion that such is the case is due to at least two reasons: (1) Sodium silicate solutions give an alkaline reaction with all common indicators. (2) Several investigators have stated that sodium silicate is completely hydrolyzed in dilute solutions.² Another possible reason is that some reference books³ give the composition of "water glass" as $\text{Na}_2\text{Si}_2\text{O}_5$. At least one chemist has calculated that the excess of sodium oxide over that required for this formula was present as free alkali.

These facts do not afford sufficient evidence on which to base the conclusion that concentrated solutions are always largely hydrolyzed. Indicators cannot be accepted as conclusive evidence regarding the amount of free alkali. Hildebrandt⁴ states that "the hydrogen ion concentration at which indicators change color may be very different from the values given by Salm and others when certain substances are present." His conclusions were based on experiments by himself⁵ and by Rosenstein⁶, which showed that the presence of other materials threw "the color change off whole powers of 10 from the tabulated values." Prideaux also calls attention to the fact that colloids and neutral salts affect the color changes of indicators.⁷ Cameron⁸ found that soils and absorbent cotton gave acid reactions with litmus even though the latter was neutral and the former yielded an alkaline extract. He concluded that the discrepancy was due to selective adsorption. These results show that the indicator method may give erroneous ideas as to the amount of free alkali present.

Furthermore, the conclusion that dilute solutions are completely hydrolyzed does not mean that the same is true of concentrated ones. In fact, it is known that salts of weak acids with strong bases are increasingly hydrolyzed on dilution.⁹ Convincing evidence of such decomposition in the case of sodium silicate was obtained by adding water to a concentrated solution. Thread-like lines immediately wriggled up through the clearly defined water layer. This showed that some material was being dissolved rapidly. This process gave

rise to a layer of flocculent material between two clear solutions. If the dilution was not too great, the flocculent material slowly dissolved when the container was shaken. But on great dilution the precipitate could not be put into solution again. Ordway¹⁰ showed that the precipitate salted out of sodium silicate solutions became more siliceous on dilution and concluded therefrom that the silicate was decomposed by water.

When any of the usual methods¹¹ for the determination of the degree of hydrolysis is applied to sodium silicate solutions, it must be remembered that such solutions are colloidal and, therefore, two-phase systems. Ultramicroscopic examination proves the presence of the tiny particles which are present in the continuous phase of aqueous liquor. These particles have selectively adsorbed certain ions from the continuous phase. Since the particles move toward the positive pole when subjected to a potential gradient, it is assumed that the hydroxyl ions are adsorbed. This negatively charged particle attracts the positive sodium ions less strongly. The net result is that at the interface between the two phases there is a higher concentration of alkali than elsewhere in the system. Since the sodium ion is bound to the particle, it seems doubtful whether it can be called "free alkali." The arrangement is shown diagrammatically herewith. Possible ions other

ARRANGEMENT OF THE POSITIVE IONS AROUND THE NEGATIVE COLLOID PARTICLES

than sodium and hydroxyl are not shown. It may readily be seen that this structure will lead to inconsistent results when different methods are used to determine the degree of hydrolysis.

The structure is especially important when indicators are used, as different indicators will not be affected in the same way by the colloidal particles. Suida¹² has shown that hydrated silica and silicates adsorb basic dyestuffs but not acidic ones. Hence, when an acid dyestuff is used as an indicator, the alkali will be determined in the continuous phase; with a basic one, the higher concentration at the interface will be found.

Bogue¹³ has recently pointed out that the conclusion of the previous investigators¹⁴ that sodium silicate was completely hydrolyzed in dilute solutions is open to question. Experiments with the hydrogen electrode indicate hydroxyl ion concentrations below those which would occur if there were complete hydrolysis. In one-hundredth molar solution of the commercial grades of sodium silicate, this method indicated that 1.58 to 9.27 per cent of the silicates, depending on their composition, had been hydrolyzed. The crystalline metasilicate, which is never used commercially, was 28.43 per cent hydrolyzed. The accompanying table gives the concentration of sodium hydroxide in various solutions calculated from these figures.

Silicate = grams of silicate of the given formula per 100 c.c. of solution.
NaOH = grams of NaOH per 100 c.c. of solution.
It will be noted that these figures are approximate percentages.

Here again the two-phase system has its effect. The hydrogen electrode probably measures the concentration of hydroxyl ions in the continuous phase. The rest of these ions are tied to the disperse phase in such a way that they cannot be considered as part of the "free alkali." As very little was known about colloids when the earlier experiments were performed, the possible effect of such structures was not considered. As Bogue has pointed out, the particles may help to carry the current¹⁵ and thus explain part of the discrepancy.

Other factors probably influence the degree of hydrolysis. In general, higher temperatures increase it. The treatment which the sodium silicate solution has received will also have an effect. If, for example, the solution is heated, then cooled, the amount of free alkali will be different than before the application of heat.

From the above discussion it is evident that the determination of free alkali is a different matter which depends on many factors. Although the hydrogen electrode is probably the best method, it is not satisfactory for all purposes, so there is no good general method. Any attempt to determine the free alkali should be carried out under as nearly the same conditions as those under which the sodium silicate is to be used. For example, if the solution is to be used for the manufacture of fiber board, the determination should be made on a sample of the solution at the average concentration and average temperature of the silicate tank on the combining machine.

To be successful, any method will of necessity take into account the factors discussed above.¹⁶

Note on the Properties of Antimonial Lead

BY LOUIS J. GUREVICH AND JANE S. HROMATKO

IN CONNECTION with the investigation of the physical characteristics of lead-plates of storage batteries, it became advisable to investigate the effects of small amounts of antimony on the physical properties of lead. The following physical properties were studied: 1, temperature of melting; 2, hardness; 3, tensile properties; 4, microstructure.

The melting temperature interval of antimony-lead alloys was investigated with a view to determine the possibility of substitution of the melting point test for the chemical analysis in the determination of the composition. A series of eight alloys the antimony content of which varied from 2.76 per cent to 10 per cent were made up. The melts were made on 20-g. samples in carbon crucibles so as to keep all other impurities out of the alloys. A precision potentiometer was used to obtain the necessary data for plotting the

FIG. 1. INVERSE RATE COOLING CURVES.
I—ALLOY B. II—ALLOY F.

inverse rate cooling curves, as described in the authors' previous paper on "Tin Fusible Boiler-Plug Manufacture and Testing," published in the *Transactions A.I.M.E.*, vol. 152, p. 1351.

The cooling curves of the alloys indicate that no definite melting point occurs in these alloys; this can be seen from the results obtained for Table I. There is only retardation in the rate of cooling extending from the temperature of complete liquefaction, or the liquefaction point, of the alloy to the minimum or the temperature of the formation of the eutectic of the alloy. Fig. 2 shows that antimony lowers the melting point of lead to such an extent that the presence of 9.88 per cent of antimony lowers it from 327.4 to 262 deg. C. These data are similar to those obtained by previous investigators.¹ The temperature interval of melting as shown in curves I and II of Fig. 1 in the

H	2.76	310.2-247 2 310.2-248.1 Av. 310.2-247.8
Reference Lead	0	327.4

place of definite critical points, indicates that approximate results only could be obtained in calculating the composition of the alloy from the temperature of incipient fusion of the inverse rate cooling curves, the construction of which takes a considerable length of time, as each must be checked by supplementary inverse rate cooling curves. The curves in Fig. 1 are plotted with the ordinates as temperature indicated by millivolts with a copper-constantan thermocouple and the abscissæ as the number of seconds necessary for the specimen to lower by an amount equivalent to 0.5 millivolt.

HARDNESS

The hardness of the alloys used for the melting-point determination was obtained on a small dead-weight Brinell hardness machine using a 5-mm. ball and a total pressure calculated to be 42.5 kg. Table II shows that there is a gradual increase in the hardness of the alloy as the percentage of antimony present increases.

TENSILE TESTS

For the determination of the tensile properties a series of alloys were prepared containing from 3 to

25 per cent antimony. These alloys were cast in an iron chill mold in form of 7/8-in. round bar, 11 in. long, from which two standard 0.505-in. diameter specimens were prepared. The tests were made on a 20,000-lb. Olsen tensile-testing machine operated at a very low rate of speed, the pulling head moving at the rate of about 0.078 in. per minute. The results of the tests given in Table II and Fig. 3 show that the presence

FIG. 3. TENSILE AND ELONGATION TESTS OF ALLOYS CONTAINING FROM 3 TO 25 PER CENT ANTIMONY

of antimony up to 10 per cent increases the tensile strength. Further addition of antimony decreases the tensile strength. The alloy containing 4.5 per cent antimony has the greatest amount of reduction of area, making it also the most ductile.

MICROSTRUCTURE

The second series of alloys, those used for tensile tests, were examined under the microscope after the specimens were properly prepared for the examination.

TABLE II. TENSILE PROPERTIES OF ANTIMONY-LEAD ALLOYS					
Alloy No.	Chemical Composition, Per Cent Sb	Tensile Strength, Lb. Per Sq. In.	Elongation in 2 In., Per Cent	Reduction in Area, Per Cent	Brinell Hardness
Reference Lead	0				3
3	2.6	4,490	15.0	21.6	5.8
H	2.76				5.8
4	3.9	5,270	19.0	25.0	5.8
G	3.94				5.8
5	4.5	6,200	35.5	34.5	6.2
F	4.8				6.2
6	5.0	6,290	28.5	27.3	6.3
E	5.42				6.3
7	6.1	8,750	21.8	23.3	6.5
D	6.4	7,100	21.8	20.8	6.5
8	6.52				6.5
9	7.4	7,050	19.3	21.0	7.0
C	7.68				7.0
10	8.1	7,455	21.5	22.1	7.2
B	8.6				7.2
A	9.88				7.3
11	9.9	7,675	15.5	13.6	
12	12.6	7,350	11.0	10.6	
13	14.0	7,025	8.8	9.3	
14	19.6	6,250	1.8	1.5	
15	24.7	6,065	1.3	0.4	

The results of the examination corroborate the results obtained by previous investigators. The microstructure was found to consist of a ground mass of eutectic with an excess of lead in the alloys numbered 3 to 11 inclusive of Table II. Alloy 12 showed traces of excess antimony, and the remaining alloys showed increased amounts of free antimony.

CONCLUSION

1. Melting point determinations are too indefinite to be used as a basis for calculating the composition of lead-antimony alloys.
2. The addition of antimony increases the hardness of the alloy.
3. The maximum tensile strength of the lead-antimony alloys is reached with an alloy containing 10 per cent antimony.
4. The alloy containing 4.5 per cent antimony gives the greatest reduction of area and is the most ductile.

More Miles Per Gallon*

A Discussion on Carburetion as Affecting Motor Efficiency, Brake Horsepower and Work—Spark Timing and Brake Load—Relation Between Torque and Engine Speed—Possibilities of More Efficient Utilization of Motor Fuels

By O. C. BERRY

SO MUCH has recently been said about the possibility of fuel shortage that most of us probably have the facts clearly in mind and have formed an opinion as to what we expect to see happen. Our viewpoints will differ, however, so that there will be nearly as many opinions as there are people present, but I feel sure we can all agree that the threatened fuel shortage will not take place this year nor next and that we can expect to experience at least the first effects of a real shortage within the next ten or fifteen years.

The past growth of the automobile industry would have been impossible had it not been for an abundant supply of cheap fuel. So rapid has been this growth that in a single generation we are consuming annually approximately four billion gallons of gasoline in the United States, and our Bureau of Petroleum Technology estimates that our known petroleum reserves are 40 per cent exhausted. We have not yet reached the point where we can expect a sharp increase in prices, however, as production is still able to keep pace with demand, and the price of any commodity tends to follow one of two standards:

When the raw material is plentiful and generally available, the price of the finished product will tend to be the cost of production plus a reasonable profit.

When the raw material is hopelessly inadequate, the price of the finished product will tend to rise until it represents all that the user is willing to pay rather than be utterly deprived of the product.

I feel safe in making the prediction that the production of gasoline in the United States will not be able to keep ahead of the demands of our growing automotive industry for as many as fifteen more years, so that the shift toward the utility value of gasoline as a measure of its price will be taking place in less than that time. We will soon see the time when any man who rides in an uneconomical car is not only paying too much for his ride and forcing up the price of fuel, but is also forcing some neighbor to stay at home for lack of the fuel he has wasted. In France at the present time gasoline is selling at \$1.90 per American gallon. What can we rich Americans expect to pay when our supply runs short?

POSTPONING THE INEVITABLE FUEL SHORTAGE

From present indications it would seem that a fuel shortage is inevitable, but there are many things we can do to postpone it and to lessen its ill effects when we are forced to face it.

We can hunt for new petroleum deposits, and thus increase our available supply of raw material.

We can learn how to cut down the present wastes in mining and storing petroleum.

We can learn how to produce more gasoline per barrel of petroleum used at the refineries.

We can learn how to make substitute fuels on a large scale and at a low price.

We can learn how to get more out of each gallon of fuel we use.

We must depend upon the mining engineer and the "wildcatter" to locate more oil deposits and upon the petroleum technologist and chemist to prevent wasting the oil during mining and storing operations. To the chemist we owe what we know about the methods of making our most effective substitutes for gasoline—benzene and alcohol—and to him we must look for our future help along these lines. The discovery of an economical method of producing shale oil or an efficient method of making alcohol from farm wastes would prove a great help. The latter would be almost a complete solution for our problem. We commend these problems to this great body of scientists.

It is my purpose not only to point out what the chemist can do to make it possible for the world to ride in automobiles, but to stimulate him to action by pointing out what the automotive engineer has done and is doing. You will be interested to know that it is possible to nearly double the miles per gallon of the American automobile. In a recent economy test in France a Voisin limousine weighing 5,300 lb. went 28.3 miles per American gallon. A Citroen car weighing 2,500 lb. went 53 miles per gallon and a 1,200-lb. Peugeot went 76.9 miles.

Contrast these figures with the performance of the average American car and you will see that our room for improvement is indeed great. Probably there is no one feature of our cars that has received less of the careful attention of our engineers in the past than has their capacity for economical running. There are no features incorporated in foreign cars for fuel economy that we do not know about and understand and I do not concede for a moment that the foreign engineer is one whit more resourceful or well-informed than the American. It is therefore up to us to look the situation squarely in the face, and recognizing the importance of fuel economy, to make a careful study of all of the factors influencing miles per gallon and to see to it that every possible improvement is incorporated in the design of our future models. With these facts in mind, I have set about making such a study and am pleased to be able to present some of the information I have got together.

CARBURETION

One of the outstanding reasons for the poor mileage of the average American car is poor carburetion, or more accurately poor carburetor adjustment. In order to make this clear it will be necessary to show

*Paper read at the Automotive Symposium, American Institute of Chemical Engineers, Detroit, Mich., June 23, 1921.

the effect of the richness of the fuel mixture on the power and economy of an engine. In studying this point, use was made of a Willys-Knight engine mounted on an electric dynamometer. The results of these tests are shown by the curves in Fig. 1. In these curves the pounds of gasoline per pound of dry air in the fuel mixture is plotted horizontally and brake horsepower and per cent thermal efficiency vertically. In carrying out these tests the throttle was arranged so that it could be securely fastened, and all of the tests were run at a constant engine speed. The gasoline was weighed to the one-hundredth part of an ounce, the air metered to the tenth part of a cubic foot, and the brake-load, speed, temperatures, etc., were carefully measured. Under these conditions and with the carburetor adjusted to give a rich and powerful mixture, the first test was run. The power, efficiency and mixture ratio were then computed and a point established on both the power and efficiency curves. The gasoline adjustment was then made slightly leaner, the brake-load adjusted to produce the correct speed and a second test was run. This procedure was repeated until the mixture became too lean to allow proper engine performance. More gasoline was then introduced each time until the mixture was entirely too rich. The mixture was

FIG. 1. EFFICIENCY AND BRAKE HORSEPOWER CURVES

thus made alternately richer and leaner until a sufficient number of points had been located on each curve to indicate quite clearly the effect of the richness of the fuel to air mixture on both the power and the efficiency of the engine.

It will be noted that there is a wide range of mixtures through which the richness has but little effect on the power of the engine. The lean and the rich mixture give equally good power and both result in what seems to be perfect engine performance. This accounts for the fact that the comparatively crude carburetors of earlier days gave quite satisfactory performance.

The range of mixtures giving the highest efficiency is very narrow, and corresponds to about the leanest mixture with which the engine will run without missing. As more gasoline is added the efficiency drops off very rapidly, so that the richest mixture producing full power will result in only about half maximum

efficiency. This explains why it is that of two cars of the same make and both performing nicely, one may go nearly twice as many miles per gallon as the other.

WHY OVER-RICH MIXTURES ARE USED

There are several reasons why so nearly all of our carburetors are adjusted so as to give too rich a mixture when the engine is hot.

Gasoline flows much more slowly when cold than when warm, so that an opening large enough to deliver the required charge to a cold engine will inevitably deliver too much when the engine is warmed up.

Cold air is denser than warm air, so that the weight of air delivered through the air opening in a carburetor will be greater when the air is cold than when it is warm, thus causing the mixture to become richer as the temperature of the engine increases.

For these reasons the mixture furnished by a carburetor with a fixed adjustment will become richer as the temperature rises. To make matters worse, not nearly all of the gasoline in a cold mixture is vaporized so that it can be burned. This makes it necessary to supply a considerable excess of fuel in a cold mixture to get the engine to run at all.

The American public has been taught to demand a car that will start easily in any kind of weather and continue to run without requiring any attention or adjusting. They have been supplied with a large variety of non-adjustable, or what has aptly been termed "foolproof" carburetors. These carburetors will deliver a mixture rich enough to start well in cold weather, and due to the great range of the explodable mixtures of gasoline and air, will keep the engine running with full power and seemingly perfectly in summer or in winter. The only fault to be found is that when the engine is hot the mixture is often 50 to 75 per cent richer than necessary and the miles per gallon are correspondingly low. A non-adjustable carburetor cannot be made so that it will make starting easy and also give high efficiency in driving.

DASH ADJUSTMENTS

A carburetor adjusted for maximum economy on a hot engine will be too lean to start when cold. There are two ways in common use for meeting this situation.

A choke may be supplied that can close off the main supply of air to the carburetor, thus enriching the mixture.

A means of adjusting the carburetor may be connected up to the dash or the steering post of the car.

The action of the choke is very severe. It causes raw gasoline to be sucked into the engine in large quantities. Its action becomes increasingly severe as the engine speeds up, so that if the mixture is rich enough to start the engine it will be much too rich after considerable speed has been obtained.

The dash adjustment may be made very satisfactory in its action if correctly used, and quite convenient as well. Its use is easily understood, as the idea is to get it set as lean as possible, and it is very easy to tell when it is too lean, as the engine will lose power and fire back through the carburetor. A proper dash adjustment set right for one speed and load will be correct at all speeds and loads at the same temperature, and will need to be changed only as the

temperature changes. The mixture should be just right for a hot engine with the dash adjustment set at its leanest position.

DISCUSSION OF CURVES

The curves in Fig. 1 show that a richer mixture is required for maximum power than for maximum efficiency. It is therefore obvious that a carburetor adjusted for maximum "miles per gallon" will be too lean to give the full power of the engine. This difficulty can be got around in this way: When driving on a level road at any speed that the law allows the engine is never called upon to deliver nearly its full power. Under these conditions the most important consideration is economy. When a steep hill is to be climbed, acceleration is desired or a neighbor wants to race, full power is the important thing. The constant speed driving is done with the throttle pretty well closed and the power work with the throttle wide open. It is possible to design a carburetor that will furnish the engine with the most economical mixture at all ordinary speeds on a hard, level road, and with the most powerful mixture when the throttle is wide open.

The fuel is almost never entirely vaporized in the intake manifold of the engine. A considerable portion flows along the manifold walls as a liquid, and lags behind the air that passed through the carburetor with it. When the engine is idling this layer of liquid is very thin, but under full load it usually forms quite a large stream. When the engine is put under load quickly, the air rushes ahead, leaving at least a portion of liquid on the manifold walls. If the mixture is lean enough to be efficient under steady running conditions, this temporary impoverishment will often be sufficient to stall the engine. It is therefore necessary to incorporate into the design of the carburetor some special means of temporarily enriching the mixture during acceleration. There are many types of construction in use, some of which are very satisfactory. It is therefore possible to get perfect acceleration even when using a mixture lean enough for maximum efficiency. The more perfect the manifold design the easier this becomes, and with the very best manifolds very little special provision is necessary for acceleration.

THE IDEAL CARBURETOR

In my estimation the highest type of carburetor yet developed for our American gasoline will meet the following requirements:

It will furnish the engine with the most efficient mixture when the car is driven at a constant speed on a hard, level road.

It will furnish the engine with the most powerful mixture when the throttle is wide open.

It will make perfect acceleration possible, even when adjusted for maximum economy.

It will have a dash adjustment that will make starting and warming up an easy matter, even in the coldest weather.

There are carburetors on the market meeting all of these requirements. They make much better "miles per gallon" possible, as well as being more satisfactory to handle than the cruder "foolproof" varieties.

THE TIMING OF THE SPARK

The second factor influencing the economy of the automobile is the timing of the spark. If the spark

passes too early it will lessen the power of the engine and tend to produce what is called a "spark" knock. If it passes too late it will also reduce the power of the engine. The proper timing of the spark in any given engine will vary with two things—the load the engine is carrying and the speed at which it is running. The latter fact is pretty generally understood, and nearly everybody knows that the faster an engine runs the earlier the spark must pass to give best results. The former fact has received comparatively little attention and will therefore be enlarged upon at this time.

In making a study of this point an engine was mounted on an electric dynamometer in such a way that the exact time of the passing of the spark could

FIG. 2. DEGREES ADVANCE OF SPARK OVER FLYWHEEL AND BRAKE-LOAD

be read, as well as the speed of the engine and the brake-load carried. The engine was run at a series of different spark settings at each of a series of different throttle openings. The results of these tests are shown in Fig. 2. In these curves the lead of the spark in degrees on the flywheel is plotted horizontally, and the brake-load carried is plotted vertically. All of the tests were made at 1,000 r.p.m. Each curve was made at a constant throttle opening, the brake-load being changed along with the spark timing to keep the speed constant.

It will be noted that a lead of 20 degrees is required for maximum power at full throttle, and a lead of 25 degrees will result in a knock. As the throttle is gradually closed the lead required for highest power is gradually increased until with the lightest load carried, a lead of 40 degrees is required. At this throttle opening the engine will carry only 60 per cent as much load with a 20 degree spark lead as it does with a 40. It is so disagreeable to have an engine knocking during acceleration and hill climbing that the spark is almost never advanced beyond the point where knocking occurs at full load. Since the engines in our American cars run at such a low per cent of their power capacity, the spark is timed much later than it should be for greatest economy, resulting in a considerable loss in miles per gallon.

The vacuum in the intake manifold of an engine varies in almost inverse ratio with the brake-load carried. It therefore follows that the lead required by the spark at a light load beyond that required at full load will vary directly with the intake manifold vacuum. This fact has been made use of in produc-

ing an automatic device for changing the time of the spark to correspond to the load carried. This device, when properly installed together with a standard controller compensating for speed, provides a completely automatic means of timing the spark that is very accurate. This device is not on the market at the present time, but I have personally conducted a series of tests showing its merit, and feel confident that it will be perfected and presented to the public in the near future. When properly installed it should add considerably to the economy obtained by the average driver.

THE LOAD ON THE ENGINE

Another opportunity to improve the economy of our automobiles has to do with the large reserve power in the engines. A good American car can climb a steep hill in high gear, and accelerate very rapidly.

This delightful "activity" necessarily means that under ordinary driving conditions on a hard, level road the engine is called upon to exert a very small per cent of its full torque capacity. In order to get accurate information on this point, a car was chosen of a make known to be carefully designed, well built and a good average accelerating ability, about 3.2 ft. per sec. per sec., and tests were made showing the torque capacity of the engine and the power required to propel the car at varying speeds. The results of these tests may be taken as representing the average performance of good American cars.

The method of conducting the tests was to insert between the carburetor and intake manifold a plate having a hole drilled through it that would serve as a throttle opening. A determination was then made of the maximum speed the car could attain on a long stretch of hard, level road with this orifice in place. This test was repeated with a number of orifices of different sizes. With the engine removed from the

at that speed with that orifice, as shown by the dynamometer tests. The results of these tests are shown in Fig. 3. In these curves the engine speed is plotted horizontally and the brake-load is at a radius of 15.1 inches vertically. The upper curve shows the torque capacity of the engine and the lower the torque measured at the flywheel of the engine that is required to propel the car at corresponding speeds. The distance between the upper and lower curves is therefore proportional to the reserve power of the engine and represents its ability to accelerate rapidly or climb a steep hill.

In this particular car an engine speed of 1,000 r.p.m. corresponds to twenty miles per hour. It will be noted that at this speed only about 14.7 per cent of the torque capacity of the engine is used when driving on a good road. Any one familiar with the performance characteristics of an engine knows that this fact alone will account for a large reduction in the thermal efficiency obtainable from the engine under ordinary driving conditions. This is such an important consideration that a special series of tests was carried out to show the exact situation.

EFFICIENCY AT DIFFERENT LOADS

It is well known that the brake thermal efficiency of an engine varies from zero at no load to a maximum which occurs at a little less than full load. Engines differ in their ability to perform under different conditions, according to their design, some doing comparatively better at light loads and others at full load. Tests were therefore carried out on the engine previously used, to determine the effect on its thermal efficiency of changing the load.

The engine was installed on the dynamometer and run at 1,000 r.p.m. and at a series of different throttle openings. At each throttle opening a series of tests was run at different carburetor settings, similar to the tests plotted in Fig. 1, and showing the mixture corresponding to highest efficiency at that throttle, together with the corresponding power and efficiency. The brake-load was expressed in terms of brake mean effective pressure, and a curve was drawn through the points showing the highest efficiency at each load. This curve is shown in Fig. 4, and indicates the maximum efficiency obtainable with this engine at each brake-load, the engine running at 1,000 r.p.m. The efficiencies will vary as the speed is changed, so that this curve should be interpreted as applying only to the one speed.

The carburetor was adjusted lean enough to give maximum economy at all loads until the throttle was wide open. After this point was reached the increases in power had to be obtained by enriching the mixture, until the full power was obtained. These richer mixtures result in reduced economy, thus causing the curve in Fig. 4 to show a decided drop as full power is approached. This curve therefore offers one more illustration of the importance of using lean mixtures when high economy is desired.

Fig. 4 shows how important it is to run the engine under a comparatively large per cent of its full load capacity. Since the miles per gallon of any car under given running conditions will vary directly with the thermal efficiency of the engine, a change in the load factor on the engine can result in greatly increased economy. This fact was checked in part by installing a different rear axle ratio and noting the

FIG. 3. RELATION BETWEEN TORQUE AND SPEED OF ENGINE

car and connected to an electric dynamometer, tests were run to determine the torque capacity of the engine at varying speeds with each of the orifices in place. Knowing the size of the rear wheels and the gear ratio, the engine speed corresponding to any car speed is accurately known. The torque required to drive the car at any one of these maximum speeds for a given orifice is the torque capacity of the engine

change in the car economy. The standard ratio was $4\frac{1}{2}$ to 1, and resulted in a load factor of 14.7 per cent at a speed of twenty miles per hour. Under these conditions the car could go 28 miles per gallon when loaded so as to weigh 3,100 lb. A gear ratio of $2\frac{1}{2}$ to 1 would result in nearly twice the former load factor, and Fig. 4 shows that this should result in

FIG. 4. EFFICIENCY OBTAINABLE AT EACH BRAKE-LOAD

an increase of about 50 per cent, or 42 miles per gallon. Under test the car actually ran 43 miles per gallon. These tests were all made with a carburetor equipped so as to make starting easy in cold weather, through the use of a dash adjustment.

ADVANTAGES AND DISADVANTAGES OF AN ADDITIONAL GEAR SPEED

Efficiency and a great ability to accelerate cannot be obtained at the same gear ratio. The former requires that the engine run at a high per cent of its torque capacity and the latter requires the other extreme. We cannot afford to compromise the delightful activity of our cars. On the other hand I feel confident that the first company to produce a car with the activity we are used to and which is also capable of going more miles per gallon than any other car of its weight in the country will become both rich and famous. We can accomplish this if we have four speeds forward. Third speed could be called the "power" or "speed" gear and the fourth the "economy" gear. Such an arrangement would be a benefit in the following ways:

It would greatly increase the miles per gallon.

It would reduce the engine vibration at the common touring speeds.

It would increase the speed at which one could tour with comfort and satisfaction on good roads.

It would enable one to tour at high speeds with the mental satisfaction that would result from knowing that one is not punishing the engine, while any other car at the same speed would be going entirely too fast for its own good.

It would greatly reduce the wear on the engine, thus prolonging its life and reducing maintenance costs.

The disadvantages are the following:

The four-speed transmission would be expensive when sufficiently well made to be quiet on two gears.

The gears would have to be shifted more often.

The possible advantages are therefore fundamental and far-reaching, and the disadvantages are of a practical nature, and though difficult, still I do not feel that they will be beyond our engineers when they really get interested in mastering them.

Our knowledge of how to increase car economy is not yet complete. There are factors influencing miles per gallon that are not mentioned here. This paper is merely a progress report presented at an early stage. I feel, however, that it has gone far enough to demonstrate the value of the study and warrant a conviction that American engineers can be depended upon to produce cars in the future showing economies that would now seem almost impossible.

In conclusion allow me to repeat that a fuel shortage in the near future is inevitable, but that its ill effects can be greatly lessened by taking the right steps at the present time. By lessening wastes in mining and storing petroleum, by perfecting the processes of making gasoline and especially by developing ways of producing substitute fuels economically and in large quantities, the chemists of the country can help make it possible for future generations to ride in automobiles. In the meantime the engineers will be steadily increasing the economy of our cars and thus adding greatly to the value of each gallon of available fuel.

Legal Notes

BY WELLINGTON GUSTIN

Company Held Not Responsible for Injury to Employee by Explosion in Gas Pipe Line

A question of negligence is decided in favor of the employer by the Supreme Court of Appeals of West Virginia in the case of Miller vs. the United Fuel Gas Co., reversing the trial court. (106 S. E., 421.)

Miller charged negligence on the part of the company in failing to keep its pipe line in a reasonably safe condition and state of repair and in permitting too great a volume of gas to remain in the pipe at high pressure; and in failing to lay a line sufficiently strong to carry with reasonable safety the volume of gas transported through it. Miller was injured by an explosion of gas in the pipe line while working about the pipe, and he brought an action for damage.

In its holdings the Court of Appeals says there was no evidence that the pipe line was improperly constructed or maintained. On the other hand, the company had constructed it only six months before the accident, and in its construction had used none but new material, obtained from La Belle Iron Works of Toledo, Ohio, the manufacturer, whose test showed a resistance sufficient to withstand a pressure of 1,500 lb. for each square inch of surface. The superintendent in charge of the work testified to its proper construction. The explosion did not occur at a coupling, but in the pipe itself, near a point where it was bent to conform to the curve of an embankment over which it ran. There was nothing to show that the pipe was improperly strained in bending or that the work was

done carelessly or negligently, but evidence to the contrary was brought out.

Failure to shut off the gas pending the search for the leak does not alone constitute negligence, because the usual way to locate a leak in one of several pipes forming part of a pipe line system is by means of the escaping gas. Though tested to withstand a pressure of 1,500 lb., the line on the day of the accident did not carry more than 350 lb.

The court said that under these facts, with the absence of any knowledge on the company's part of a fatal defect likely to cause such an accident and the failure on the part of the claimant to show by proof that it was due to some negligent act or omission to act on the part of the defendant, there is nothing to support a finding of liability against the company. The claimant was engaged on a dangerous work and well knew the risk and hazard attending it; therefore, before he can recover for the injury he must show actionable negligence on the part of the company.

When the employer has exercised reasonable care and diligence in providing a reasonably safe place within which his employees may perform the work assigned to them, he has fulfilled his duty to them in that regard. (99 S. E., 75.)

Only Attempt to Sell Goods as Another's Is Unfair Competition

A question of unfair competition in marketing one's product came up in the case of the Upjohn Co. vs. The William S. Merrell Chemical Co., a decree for the defendant being affirmed in the United States Circuit Court of Appeals, 269 Fed., 209.

It appears that plaintiff had marketed its product by extensive advertising and selling throughout the United States in 1908, when defendant's salesmen found the product on the market and sent in to the house samples of plaintiff's article. Defendant thereupon decided to make the same thing in the same form, with the expectation that it would thereby be able to fill with something "equally as good" a part of the demand which the plaintiff company was creating. To this end defendant put up an article which was indistinguishable from plaintiff's, but it did not use the latter's trade name or mark, and put the product up in bottles or packages bearing its own name as manufacturer.

It was not claimed that in the bottles or cartons, or anything except in the product itself, was there fraudulent imitation or unfair competition. Nor was it denied that defendant had, inherently and originally, the same right plaintiff had to select from the common stock this particular size, shape and color for its product.

WHEN IMITATION IS UNFAIR COMPETITION

The court said it was well settled by decisions of the U. S. Supreme Court that a plaintiff is entitled to relief against unfair competition only where defendant attempts to palm off on the purchasing public his goods as the goods of the plaintiff; that where the imitation relates only to matters as to which the defendant has, *prima facie*, a right equal to plaintiff, there must have been a public acquiescence in plaintiff's appropriation of these things for his product—whereby they have become indicia of origin, to make the imitation unfair competition.

That while, when the plaintiff has selected as his means of identification words or marks that are arbi-

trary and hence proper trade marks, his title is at least initiated by the appropriation; yet as to those means of identification which are descriptive or which for any reason are known and open to all there is no basis in principle or authority for the creating of a title of quasi-exclusive right in plaintiff, except the theory that there has been this public sanction of plaintiff's appropriation, by acquiescence which has continued long enough and under circumstances suitable to raise a presumption that the public concedes the right and to make it inequitable and unfair thereafter to dispute it.

The court said there were plenty of other sizes, shapes and colors than plaintiff's which defendant might have adopted; it must have copied plaintiff's complete combination because it expected to get commercial benefit from the copying. But this is not enough, says the court; to be condemned it must have expected to practice a fraud or contribute to the practicing of it.

The situation must be judged as it existed when defendant introduced his copy of the product, and the fact that plaintiff's product, whose appearance and composition were alike open to everybody, had been in the hands of distributors for a few months does not establish a sanction by the consuming public of plaintiff's appropriation of that composition and appearance for its own use and product sufficient to prevent its subsequent appropriation by the defendant.

Many cases were cited supporting the claim of unfair competition, and the court granted that each case depends so absolutely upon its own circumstances that a controlling precedent is not to be expected. Each of the cited cases upon which plaintiff specifically relies depends upon the finding that the consuming public had come to regard the trade dress as indicating that the thing was the article which it was in the habit of buying and wanted to get.

REASONING BY THE COURT

Further the court says: "Perhaps the result which we reach in this case, rested as it is upon the fact that defendant copied the product and began its competition before there was time for plaintiff to get the indicative effect of its trade dress sufficiently established, is most severely tested by saying that this would make the diligent thief immune, while the one who might hesitate and delay must give up his plunder. The answer is that there can be no larceny unless the title or possessory right of the first holder is better than that of the second taker"—and that in this case, until the general public belief among users that any product of this appearance was plaintiff's product connected with its trade name had come into existence, plaintiff's title to this combination of characteristics was no better than defendant's.

To establish unfair competition by copying the appearance of plaintiff's product, it is necessary that the appearance has received such sanction as to identify the article sold under plaintiff's trade mark or name.

As to the injustice in a state of the law which denies protection to a plaintiff who has expended \$30,000 and more in introducing to the public his peculiar form of product, the court points out that in this case the expense indivisibly inured to the advantage of the trade mark; and in any case it says it may be a lesser evil that plaintiff must fail of full protection than that free choice of common form should be denied to competitors. No unfair competition was found.

Definitions of Physical Terms

BUREAU OF STANDARDS Circular 100, on "Nickel," (published in large part serially in *CHEMICAL & METALLURGICAL ENGINEERING*, beginning Jan. 5, 1921) contains the following definitions of physical constants. These have often been determined for various metals and alloys:

Absorption Index.—When monochromatic light traverses a distance equal to its own wave length, λ , in a material, is the ratio of the amplitude of the emergent light J'_λ to that of the entering light J_λ .

$$\frac{J'_\lambda}{J_\lambda} = e^{-2\pi\kappa}$$

when κ is the absorption index.

(A variety of usage prevails regarding the definition of this term. This definition is used in the Smithsonian physical tables.)

Density.—The density of a substance is the mass per unit volume. It is usually expressed in terms of grams per cubic centimeter.

Electrical Conductivity and Resistivity (χ , ρ).—There are two methods of expressing electrical resistivity in common use, each being defined quantitatively in terms of the resistance of a unit specimen. The volume resistivity is ρ in the equation

$$R = \frac{\rho l}{s}$$

in which R = resistance, l = length, and s = cross-section. The volume resistivity thus defined may be expressed in various units, such as microhm-cm. (microhm per centimeter cube), ohms per foot of a uniform wire 1 mil in diameter, etc. The commonly used units, in abbreviated terminology, are: Microhm-cm., microhm-inch, ohm (meter, mm.), ohm (meter, sq.mm.), ohm (mil, foot).

The other kind of resistivity is mass resistivity, and is defined as δ in the equation

$$R = \frac{\delta l^2}{m}$$

in which m = mass of the wire. The usual units of mass resistivity are: ohm (meter, gram), and ohm (mile, pound).

Per Cent Conductivity.—The term "conductivity" means the reciprocal of resistivity, but it is used very little in wire calculations. In connection with copper, however, extensive use is made of the per cent conductivity, which is calculated in practice by dividing the resistivity of the international annealed copper standard at 20 deg. C. by the resistivity of the sample at 20 deg. C.

Temperature Coefficient of Resistance.—The temperature coefficient of electrical resistance is the fractional change of resistance per degree change of temperature. Its value varies with the temperature, and hence the temperature from which the resistance change is measured must always be stated or understood. For a temperature t_1 , the temperature coefficient α_1 is defined, for a metal like copper, by

$$R_t = R_{t_1} [1 + \alpha_1 (t - t_1)],$$

in which R_{t_1} = resistance at the temperature t_1 and R_t = resistance at any other temperature t . The temperature coefficient that is usually used at 20 deg., for example, is

$$\alpha_{20} = \frac{R_t - R_{20}}{R_{20}(t - 20)}$$

Boiling Point.—The boiling point of a liquid is the

temperature at which it boils under atmospheric pressure, or better the temperature at which its vapor pressure is equal to the external pressure.

Brinell Test.—An indentation is made, by pressure, on a polished surface of the material, using a hardened steel ball. There are several ways of expressing the hardness:

The commonest definition of the Brinell hardness is the pressure in kilograms per unit area (square millimeters) of the spherical indentation. (Hardness numeral = H. N.)

$$H. N. = \frac{\text{Pressure}}{\text{area of spherical indentation}} = \frac{P}{t\pi D}$$

$$\text{where } t = \frac{D}{2} - \sqrt{\frac{D^2}{4} - \frac{d^2}{4}}$$

P = pressure used;

t = depth of indentation;

D = diameter of sphere;

d = diameter of indentation.

Electrolytic Solution Potential (E).—At the junction of a metal and any conducting liquid there is developed a solution potential, which is a measure of the free-energy change of the chemical reaction which is possible at the surface of the metal and liquid. In particular if the chemical reaction consists in the solution of the metal, forming ions, the e.m.f. is

$$E = \frac{RT}{nF} \ln \frac{P}{p}$$

where R = the gas constant;

T = absolute temperature;

n = valence of metal;

F = 96,500 coulombs, the Faraday constant;

P = solution pressure of metal;

p = osmotic pressure of metal ion formed in solution.

In any electrolytic cell the sum or difference of two such potentials is measured, one of which may be a standard electrode; for example, the hydrogen or the calomel electrode. The e.m.f. of an electrolytic cell of the following type: Normal hydrogen electrode—solution—metal is often called the single e.m.f. (e_h) for the metal in the solution; that is, arbitrarily assuming the e.m.f. of the normal hydrogen electrode to be zero.

Emissivity (E or E_λ).—The coefficient of emissivity

E for any material represents the ratio $\frac{J'_\lambda}{J_\lambda}$ of the intensity, J'_λ , of radiation of some particular wave length or color, λ , emitted by the material at an absolute temperature T to that J , emitted by a black body radiator at the same temperature.

The coefficient of total emissivity E for any material represents that ratio $\frac{J_1}{J}$ of the intensity of radiation of all wave lengths, J_1 , emitted by the material at an absolute temperature, T , to that, J , emitted by a black body radiator at the same temperature.

This coefficient is always less than 1, and for metals is equal to 1 minus the reflection coefficient for normal incidence (Kirchhoff's law).

For any optical pyrometer using monochromatic light a value of the observed or "black body" temperature of any substance (not inclosed) is reduced to the true temperature by the following formula:

$$\frac{1}{T} - \frac{1}{T_0} = \frac{\lambda \log E_\lambda}{6232}$$

where T = true absolute temperature;

T_o = observed absolute temperature;

λ = wave length in microhm (0.001 mm.);

$E\lambda$ = relative emissivity of substance for wave length.

Erichsen Test.—This test is carried out to determine the ductility of sheets. An indentation is made in the sheet with a die with hemispherical end. The greatest depth of indentation which can be made without incipient cracking of the sheet, measured in inches or millimeters, is known as the Erichsen value for the sheet.

Heat of Fusion.—The heat of fusion of a substance is the quantity of heat absorbed in the transformation of unit mass (1 g.) of the solid substance to the liquid state at the same temperature.

Magnetic Properties.—The usual magnetic characteristics of a substance are given either by the permeability, μ , or the susceptibility, κ . Permeability is the ratio of the magnetic induction (B in gauss per square centimeter) to the magnetizing force (H in gauss per square centimeter). This is indicated by the relation

$$\kappa = \frac{B}{H}$$

Susceptibility is given, in corresponding units, by

$$\kappa = \frac{\mu - 1}{4\pi}$$

For all materials except iron and a few other ferromagnetic metals μ is very nearly unity and κ is only a few millionths. When κ is positive in sign the substance is paramagnetic, when negative diamagnetic. The susceptibility as thus defined is sometimes called volume susceptibility and indicated by κ_v . A quantity called mass susceptibility is also used, and is equal to the volume susceptibility divided by the density of the material; it is represented by κ_m .

Melting Point.—The melting or fusing point of a substance is the temperature at which it fuses (under atmospheric pressure), or more accurately the temperature at which the solid and the liquid metal are in equilibrium with each other.

Peltier Effect (π).—When at the junction of two metals current flows from one to the other, heat is in general absorbed or liberated (see "thermoelectromotive force" below); the coefficient, the amount of heat liberated when a unit quantity of electricity flows across the junction, is known as π (measured either in calories per coulomb or in volts), the Peltier effect.

Refractive Index.—The ratio of the velocity of light in vacuum to that in any material is called the refractive index (n) of that material. (This physical quantity ceases to have a meaning at or near an absorption band in the material.)

Scleroscope Test (Shore).—A hardened hammer falls from a constant height onto a polished surface of the material, and the distance of rebound is measured on a scale 10 in. long, divided into 140 equal parts. The scleroscope hardness is expressed as the distance of rebound on this arbitrary scale, the value 100 representing the hardness on this scale of hardened steel.

Specific Heat.—(σ).—The true specific heat of a substance is $\frac{du}{dt}$ when u is the total internal heat or energy of unit mass of the substance. The mean specific heat is defined as $\frac{q}{t_1 - t_2}$ per unit mass when q is the quantity

of heat absorbed during a temperature change from t_1 to t_2 . It is generally considered as the quantity of heat (calories) required to raise the temperature of unit mass (grams) by unity (degrees centigrade), either at constant volume or at constant pressure. Unless otherwise noted the specific heat of solids refers to that at constant (atmospheric) pressure. The true specific heat (constant pressure) of metals may usually be expressed sufficiently by an equation of the type

$$\sigma = A + Bt + Ct^2 + \dots$$

Tensile Test.—The quantities determined in the tension test are the following:

The *ultimate tensile strength* is the maximum load per unit area of original cross-section borne by the material.

The *yield point* is the load per unit of original cross-section at which a marked increase in the deformation of the specimen occurs without increase of load.

The *elastic limit* is the greatest load per unit of original cross-section which does not produce a permanent set.

The *proportional limit* is the load per unit of original cross-section at which the deformations cease to be directly proportional to the loads.

The *percentage elongation* is the ratio of the increase of length at rupture between arbitrary points on the specimens to this original length.

The *percentage reduction of area* is the ratio of the decrease of cross-section at the "neck" or most reduced section at rupture to the original section.

Thermal Conductivity (λ).—The coefficient of thermal conductivity (λ) expresses the quantity of heat (small calories) which flows in unit time (seconds) across a unit cube (centimeter) of the material whose opposite faces differ in temperature by unity (1 deg. C.). Its *temperature coefficient* is expressed as

$$\alpha_{t_o} = \frac{\lambda_t - \lambda_{t_o}}{\lambda_{t_o} (t - t_o)}$$

Thermal Expansion.—If l_t is any linear dimension of a solid at any temperature $\frac{dl}{ldt}$ is the linear coefficient of thermal expansivity of that solid in the direction of l . It is not in general proportional to the temperature except approximately over small temperature intervals, but may be expressed in the following manner:

$$\frac{dl}{ldt} = a + bt + ct^2 \dots$$

For small temperature intervals a mean coefficient (α) is often determined; that is,

$$\alpha_{t_o} = \frac{l_t - l_{t_o}}{l_{t_o} (t - t_o)}$$

Thermoelectromotive Force (E).—In an electric circuit composed of two dissimilar conductors, the two junctions being at different temperatures, there exists in general an electromotive force, called the thermoelectromotive force, between the two metals, the value of which is a function both of the temperature and the difference of temperature between the two junctions. It is shown thermodynamically that this e.m.f. is related to the Thomson and Peltier effects in the following manner:

$$\pi = \frac{T dE}{J dt} \quad \text{and is expressed in calories per coulomb when}$$

$$\sigma_1 - \sigma_2 = - \frac{T d^2 E}{J dt^2} \quad J = \frac{418 \text{ dynes} \times 10^6}{\text{calories}}$$

when E is the thermal e.m.f., T the absolute temperature, $\frac{dE}{dt}$ the thermoelectric power (see below), and $\sigma_1 - \sigma_2$ the difference in the Thomson effect of two materials. The form of the function $E = f(T)$ is not known. In general the equation $\frac{dE}{dt} = A + BT$ satisfactorily fits the experimental data over a limited range of temperature of a few hundred degrees.

Thermoelectric Power.—If E is the thermoelectromotive force of any two dissimilar metals, $\frac{dE}{dt} =$ the thermoelectric power; it is at any temperature therefore approximately the thermal e.m.f. of a couple of which the temperatures of the two junctions differ by 1 deg. C.

The Thomson Effect.—When a current flows in a conductor from a point at one temperature to one at another, heat is in general liberated, or absorbed, and an e.m.f. or counter e.m.f. is produced. The coefficient of the Thomson effect is the amount of heat liberated or absorbed when unit quantity of electricity flows from a point at temperature t to one at a temperature $t + dt$, and is equal to σdt calories per coulomb where σ is the so-called Thomson specific heat of electricity. It is called positive for any material when heat is generated in that material as a current flows from a region of higher to one of lower temperature.

The Oxidation of Carbon Tool Steel on Heating in Air

BY HOWARD SCOTT

Instructor in Metallurgy, Harvard University

IT IS SOMETIMES of value, from the viewpoint of both the laboratory and the shop, to know to what extent decarbonization (oxidation of carbon) and scaling (oxidation of iron) are likely to alter the structure and dimensions of carbon tool steel under heat-treatment. There seems, however, to be no systematic data in the meager literature on this subject outside of that presented by Emmons¹, who studied the effect of temperature and oxidizing medium on the depth of decarbonization. It is of perhaps equal importance to determine also the scaling and decarbonizing effect of air for various heating periods and whether the size of specimen has any effect. For this reason the experiments described here were undertaken.

The materials investigated were "Armco" iron in the form of $\frac{1}{2}$ -in. plate and a eutectoid carbon steel in the form of 1-in. round bar which gave the following analysis:

	C	Mn	Si	S	P
Armco iron.....	0.03	0.06	trace	0.021	0.004
Steel	0.86	0.51	0.04	0.040	0.024

Disks about $\frac{1}{2}$ in. thick were cut off the steel bar and ground plane and parallel to 0.001 in. on an alundum grinding wheel. One-inch square specimens were cut from the iron plate and similarly prepared. The specimens were heated in an electric muffle furnace and the duration of the heating was recorded from the time at which they reached the furnace temperature. After treatment they were cooled in lime. The scale was then chipped off the parallel faces, which were slightly re-ground until about half the surface showed metal. One-half the difference between the thickness before and after treatment was taken as the loss due to scaling.

TABLE I. EFFECT OF TEMPERATURE AND TIME ON THE SCALING AND DECARBONIZATION OF CARBON TOOL STEEL

Temperature, Deg. C.	Time, Hr.	Scaling, In.	Decarbonization, In.
780	2	0.001	0.000
780	5	.002	.000

TABLE III. EFFECT OF THE THICKNESS OF THE SPECIMEN ON THE SCALING AND DECARBONIZATION OF CARBON TOOL STEEL

Thickness, In.	Scaling, In.	Decarbonization, In.
$\frac{1}{2}$	0.008	to center
$\frac{1}{2}$	.008	0.045
$\frac{1}{2}$	.009	.049
1	.009	.045

The steel samples were prepared for microscopic examination by cutting in half perpendicularly to the plane faces and fastening together with bolts pairs which it was desired to compare. These sections were polished and etched with 10 per cent picric acid in methanol. A sharp edge was thus more easily obtained than by electrolytic deposition of copper and the additional advantage was obtained of being able to compare two specimens in the same field.

The depth of decarbonization was measured with a graduated eye-piece using a 16-mm. objective. The limit of free ferrite was somewhat irregular, so the values given are estimated averages. They are somewhat higher than those of Emmons, but this is to be expected, for he measured only to the limit of free cementite in a hypereutectoid steel.

The data obtained on the scaling and decarbonization of steel samples for various periods of heating are given in Table I and those for the scaling of iron and steel samples heated simultaneously in Table II. Table III gives the results of heating steel specimens of different thicknesses for five hours at 970 deg. C. Micrographs were also taken of representative specimens and are shown in Figs. 1 to 16.

The results for decarbonization are summarized in Fig. 17, which shows the effect of time and temperature on the depth of decarbonization as measured from the oxidized surface. The total thickness of steel affected by the oxidizing conditions is of course greater and may be obtained by adding the figures for scaling to those for decarbonization as given in the tables.

These data establish several phenomena to which attention might properly be called. First, the scaling of the "Armco" iron is greater than that of the steel under identical conditions. This is a necessary conse-

¹J. V. Emmons, *Trans., A. I. M. E.*, vol. 50, p. 405 (1915).

FIGS. 1 TO 16. DECARBONIZATION OF EUTECTOID STEEL AFTER ANNEALING AT VARIOUS TIMES AND TEMPERATURES

Figs. 1 and 2. $\frac{1}{2}$ hr. at 890 and 970 deg. C. respectively. $\times 40$. Figs. 3 and 4. $\frac{1}{2}$ hr. and $\frac{1}{2}$ hr. at 1,060 deg. C. $\times 40$. Figs. 5 and 6. $\frac{1}{2}$ hr. and 1 hr. at 890 deg. C. $\times 100$. Figs. 7 and 8. $\frac{1}{2}$ hr. and 1 hr. at 970 deg. C. $\times 10$. Figs. 9 and 10. Sample $\frac{1}{2}$ -in. and $\frac{3}{4}$ -in. thick heated 5 hr. at 970 deg. C. $\times 40$. Figs. 11 and 12. 2 hr. at 5 hr. at 890 deg. C. $\times 40$. Figs. 13 and 14. 2 hr. and 5 hr. at 970 deg. C. $\times 40$. Figs. 15 and 16. 2 hr. and 5 hr. at 1,060 deg. C. $\times 40$.

FIG. 17. RELATION BETWEEN DEPTH OF DECARBONIZATION, TIME AND TEMPERATURE

quence of the greater affinity of oxygen for carbon than for iron. Second, the size of the specimen is immaterial under the conditions of the experiment except when it is less than $\frac{1}{8}$ in. thick. Third, the same depth of decarbonization does not imply the same amount of carbon lost; thus one-half hour at 1,060 deg. C. gives the same depth of decarbonization as one hour at 970 deg. C., but the microstructure shows less free ferrite in the latter case.

Possibly the most important inference to be drawn from these results is that below about 850 deg. C. and for a period up to five hours there is no appreciable decarbonization—that is, scaling at least keeps pace with decarbonization.

In conclusion the author wishes to acknowledge the interest in this work shown by Prof. Sauveur, in whose laboratory the experiments were conducted.

Cambridge, Mass.

Outsaving the Wheelbarrow

One of the pressing business questions of the day is the elimination of industrial wastes. It is a factor that has an important bearing on the manufacturer's problem of meeting economic conditions.

Industrial waste may represent material, labor or time. Material wastes are concrete, tangible, and for this reason have received closer study. On the other hand, labor wastes and time wastes, particularly unproductive labor and time represented in the handling of material, have not, generally speaking, received the attention their importance as a definite opportunity for effecting certain economy in manufacturing justifies. That there is that opportunity has been demonstrated time and time again in specific cases. That industry as a whole, and individual manufacturers in particular, may be materially benefited through approved mechanical handling method is certain. Yet, over 90 per cent of the industrial plants in this country are still doing all or a large part of their lifting, transporting and conveying by hand labor, and it is evident that this means the annual expenditure of a tremendous amount of money, which might be used for more productive purposes.

A series of elaborate time-motion studies on the work of electric storage battery trucks vs. wheelbarrows recently made by the Yale & Towne Mfg. Co. at its Stamford, Conn., plant is a case in point.

Accurate records were first made on the cost of handling 600 tons of molding sand from a freight car on the railroad siding to the molding room in the foundry, 200 ft. away. Forty feet of this distance was a 12 per cent grade up a concrete ramp, with a sharp, right-angle turn into the shop at the top. It took eighteen men with wheelbarrows and shovels six days, working nine hours per day, to transfer the 600 tons of sand. The total cost was \$545.72.

A few weeks later another 600 tons of the same sand, delivered by car to the same point, was transferred to the molding room by means of a Yale electric truck equipped with a standard detachable end-dump body of 27 cu.ft. capacity. With one man driving the truck (one member of the former wheelbarrow gang) and an extra man with a shovel to help load the truck, this 600 tons of sand was transferred in four days, nine hours work per day, at a total cost, including interest on capital invested and charges for electric current used by the truck, of \$183.60. Thus on this one job, \$362.12 was saved. Needless to say, the mechanical way is standard practice at the plant.

The following itemized statement is interesting:

MECHANICAL METHOD

Material handled: Molding sand.	
From: Freight car.	
To: Molding room storage.	
Distance: 400 ft. round trip.	
Grade: 12 per cent, 40 ft. long.	
Capacity of Yale dump body truck: 27 cu.ft.	
Men required: To load.....	5
Men required: To unload.....	4
Men required: To operate.....	1
Total men.....	10
Total time consumed to unload shipment of 600 tons.....	4 days
Total cost of labor (9-hr. day).....	\$183.60
Demurrage charges.....	None
Total expense.....	\$183.60

WHEELBARROW METHOD

Material handled: Molding sand.	
From: Freight car.	
To: Molding room storage.	
Distance: 400 ft. round trip.	
Grade: 12 per cent, 40 ft. long.	
Capacity of wheelbarrows: 5 cu.ft.	
Men required: To load.....	3
Men with wheelbarrows.....	15
Total men.....	18
Total time consumed to unload shipment of 600 tons.....	6 days
Total cost of labor (9-hr. day).....	\$495.72
Demurrage charges (over 4 days, \$25 per day).....	50.00
Total expense.....	\$545.72

Many more examples could be cited.

Mechanical handling is one way of accomplishing more work for the same expenditure.

Nitrogen and Argon Gas-Purifying Equipment

The apparatus shown in the accompanying figure is used for purifying the nitrogen or argon used for filling the bulbs of electric lights. In this electric high-pressure nitrogen- and argon-purifying equipment, which is marketed by the Charles Eisler Engineering Co., of Newark, N. J., the gas to be purified under a pressure of 30 to 50 lb. per sq.in. passes through containers 1 and 2, electric furnace A, which holds a steel tubing containing copper, electric furnace B, containing copper oxide, and containers 3 and 4, whence the purified gas, after being reduced to 5 to 6 lb. per sq.in. pressure by means of a diaphragm reducing valve, enters the supply line.

The electric furnaces operate on 110 or 220 volts and take about 9.4 amperes each. They are separately controlled by the respective rheostats *a* and *b*. The temperature for purifying is between 500 and 650 deg. C.

The advantages of operating the apparatus under

ELECTRIC HIGH-PRESSURE NITROGEN- AND ARGON-PURIFYING EQUIPMENT

high pressure may be summarized as follows: The purifying materials react more rapidly, so that complete removal of impurities is possible, even with somewhat lower temperatures in the tubes containing the copper and copper oxide; when gas is drawn at 5-lb. pressure from purifiers operating at 40 lb. the gas is in contact with the reagents practically three times as long as when the purifiers are operated at 5 lb.; when the gas-filled furnaces are allowed to cool to room temperature the final internal gas pressure is above that of the atmosphere, so that it is impossible for air to enter the purifiers through leaks.

In starting the apparatus, from 20 to 25 minutes is required to bring the purifiers to the proper temperature. The capacity of this apparatus is equivalent to 18,000 to 20,000 100-watt lamps per day.

Synopsis of Recent Chemical & Metallurgical Literature

Industrial Combustion of Gaseous Fuel.—The April, 1921, issue of *Chaleur et Industrie* contains the first part of a paper presented by André Grebel before the Central Office of Rational Combustion. Mr. Grebel suggests three new terms which shall express the main factors involved in the study of combustion.

1. Combustive power (*pouvoir comburivore*) which shall express: the number of volumes of dry air at normal tem-

perature and pressure which are necessary for the complete theoretical combustion of one volume of gaseous fuel.

2. Comburimeter. An apparatus for measuring the comburivorous power.

3. Thermic potential, which shall express the number of calories contained in one cu.m. of the theoretical mixture of combustible gas and air at 0 deg. C. and atmospheric pressure.

The thermic potential P_{th} is given in function of the calorific power of the gas P_{co} and of its comburivorous power P_{co} by the equation

$$P_{th} = \frac{P_{co}}{1 + P_{co}}$$

The value of the thermic potential multiplied by 2.5 gives the theoretical temperature of combustion.

He describes in detail the Grebel-Velter comburimeter. In the accompanying table are summarized the main coefficients of various combustible gases.

Concrete in the Construction of Salt Plants.—An interesting example of the extensive use of concrete at salt plants is given on page 271 of the June issue of *Concrete*. The plant described is that of the Pomeroy Chemical Co., at Pomeroy, Ohio, built in 1919 by the Rust Engineering Co.

The salt beds are about 1,300 ft. below the level of the Ohio River at Pomeroy Bend, the brine, which is a 10 per cent solution with a gravity of 7 deg. Bé., being forced up into the storage tank by an air lift. From there it runs over a measuring weir to a pre-heater, where it is heated to 68 deg. C., and then through tanks in which it is concentrated to a 20 per cent solution.

The brine next passes through concrete mud-settlers and draw settlers and then into concrete grainers, where copper steam pipes concentrate the solution to 35 deg. Bé., when the salt crystallizes and can be removed by a mechanical scraper ready to be packed for shipment. The mother liquor is further concentrated in a concrete bittern grainer and pumped to stills where bromine and calcium chloride are separated.

When the plant is in continuous operation the temperature in the mud settlers is practically constant, varying only 4 or 5 deg. C. The draw settlers are subject to wider variations, since the brine level changes with the filling of the grainers. As the grainers are completely emptied when the salt is removed and are not immediately refilled, their temperature may range from atmospheric (which is sometimes zero) to 82 deg. C., or 176 deg. F.

The settler tanks are 158 ft. long, 11 ft. wide and 3 ft. deep; the grainers have the same length and width, but are only 1 ft. 8 in. deep. Due to their length, these tanks were not built monolithic, but were constructed in sections about 13 ft. long, with bell joints, which allow a smooth inner surface.

When it is remembered that in the bittern grainer the concrete is in contact with concentrated brine of 40 deg. Bé., it is evident that good concrete will withstand even concentrated brine solutions, because the plant has been in operation about two years and there are no appreciable signs of deterioration. The wide temperature range, about 200 deg. F., should also be noted.

Other successful installations are also briefly referred to in this article.

Recent Chemical & Metallurgical Patents

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Process of Extracting Catechin and Catechu-Tannic.—A process for the extraction of catechin and catechu-tannic acid from vegetable substances containing them consists in digesting the disintegrated raw material with hot water in the absence of air and preferably in an autoclave, filtering and concentrating the decoction, then cooling it in absence of air to allow the catechin to separate out, and finally evaporating the filtrate to dryness in absence of air and preferably *in vacuo* to obtain the catechu-tannic acid. The precipitated catechin is purified by washing with cold water and is then dried in the dark either by a current of hot air or by absorption of the contaminating liquid by means of sand contained in bags. As starting material, the wood of *Acacia catechu* or *Acacia sendra* and the leaves and shoots of *Uncaria gambier* are mentioned. (Br. Pat. 161,431; INDIAN WOOD PRODUCTS CO., LTD., Calcutta. June 1, 1921.)

Electric Furnace.—A crucible, tube or the like acting as heating resistance is provided at its upper end with a terminal *j* having one or more arms sliding on guide rods *j*² and partly supported by springs *j*³ to allow expansion. The lower end *g* of the crucible, which is fitted with an air-cooled terminal *h*, may rest on a disk *f* supported through a ball-and-socket or like joint from a bracket *c* secured to the casing *a*. As shown, the disk *f* has a central spherical

recess or hole to receive the rounded or pointed end of an adjusting screw *d* working in the bracket *c*. A ring *k* on the terminal is provided with a sharpened edge *k*¹ bearing on an asbestos or other packing ring *l* in a groove in the casing. In a modification, a tube resistance has a lower water-cooled terminal supported by a ring carried by three adjustable bolts attached to the casing, and a sharp-edged ring in the casing can be screwed down onto an asbestos or other ring on the top of the terminal. In either arrangement, the crucible or tube is surrounded by a filling material within a brick lining of the casing *a*. The filling material may be retained by an asbestos cover plate *o*, held by a flat

metal ring *o*¹. (Br. Pat. 161,603; MORGAN CRUCIBLE CO., LTD., and C. W. SPIERS, Battersea, London. June 1, 1921.)

Vulcanizing Rubber Oven.—An oven particularly applicable for vulcanizing india rubber is heated internally by pure hot air and may also have a jacket heated by hot air. A fan *a* supplies air through a heater *b* to the oven *d* and baffles *e* and *f* are fitted at the inlet and at the outlet *g*. By passing the combustion products from the heater to a jacket *h*¹ around the air

outlet shaft sufficient induced draft is created to dispense with the fan. An independent hot air supply is provided for the jacket by a pipe *c*¹. (Br. Pat. 161,701; F. O. BYNOE, Twickersham, Middlesex. June 8, 1921.)

Continuous Fermentation Process.—A continuous fermentation process for industrial sugar solutions consists in passing the liquid through a series of closed vessels containing filters impregnated with yeast or other ferment, the rate of flow being adjusted so that complete fermentation is effected. The order of the vessels is changed from time to time to prevent destruction of the ferment. The process is applicable to the production of butyl alcohol, glycerine, lactic acid, butyric acid, citric acid, acetone, etc., as well as ethyl alcohol. (Br. Pat. 161,870; A. ROMER, Stuttgart, and DEUTSCH-KOLONIALE GERB. U. FARBSTOFF GES., Karlsruhe. June 8, 1921.)

Lactose.—In manufacturing lactose from whey, the lactalbumen is precipitated by the addition of a substance which produces in the whey a suitable colloid. It is suggested that the precipitation is due to the production of a negatively-electrified colloid in presence of the albumen. Sodium thio-sulphate, yielding colloidal sulphur, is stated to be suitable. The whey may be heated to 70-80 deg. C. before adding the precipitant. (Br. Pat. 161,887; J. TAVROGES, J. W. ROCHE and G. MARTIN, all of Manchester. June 8, 1921.)

Coffee Extracts.—An infusion of roasted coffee is concentrated at or near 0 deg. C. in a high vacuum and the concentrated extract dried either by the circulation of air, or *in vacuo* with the aid of absorbents such as concentrated sulphuric acid or zinc or calcium chloride. The concentration may be effected on the surface of rotary disks or drums dipping into the liquid, heat being supplied by water circulating through the hollow shafts of the disks or drums, and the concentrated liquid removed by scrapers. Small quantities of lactose and dextrine may be added to the dried product. The product may be added to cocoa butter, etc. The extract may be frozen and allowed to evaporate as solid *in vacuo*. (Br. Pat. 161,920; not yet accepted; A. CHALLAS, Neuilly sur Seine, France. June 8, 1921.)

Vegetable Gelatine.—Vegetable gelatine is extracted from seaweed, specially carragheen, by first softening and cleaning the material in hot or cold water, then heating it with water containing a small quantity of an acid, such as acetic acid, a salt or an alkali, in order to break down the vegetable tissue, and after running off the liquor, adding the liquor obtained by subjecting the residue to pressure, and finally filtering the amalgamated liquors and evaporating them to dryness. The seaweed may be bleached before the breaking-down treatment; and a preservative, such as bisulphite or benzoate of soda, may be added before evaporation. The evaporation of the liquid may take place on trays, on heated rollers, or by spraying into a current of hot air. The product is of use as a food. (Br. Pat. 161,612; M. M. MALCOLM and C. S. TOWNSEND, both of London. June 1, 1921.)

Current Events

in the Chemical and Metallurgical Industries

European Interest in Chemical Exposition

That European chemical industries are intensely interested in the forthcoming Chemical Exposition in New York was ascertained by Worth Colwell, who has just returned from Europe. Mr. Colwell is one of the exposition's publicity representatives and with a member of his staff visited England, France and Switzerland. In London, after presenting the various phases of the exposition to Dr. J. P. Longstaff and Sir William Pope of the Society of Chemical Industry, assurances were given that the British chemical experts will be well represented at the American exposition when it opens the week of Sept. 12 in the Eighth Coast Artillery Armory, New York.

In France leading chemists stated that they intend to make the transatlantic trip for the event, and in Switzerland a number of experts are especially interested in the development of chemical machinery in the United States. The future of the dye industry is a topic much discussed abroad and also the fuel problem. The French are particularly interested in the latter, largely because gasoline is costly there and the matter of obtaining substitutes for gasoline or "essence" is of vital importance.

Pennsylvania Industrial Relations Conference

An industrial relations conference, authorized by Gov. William C. Sproul of Pennsylvania, is being arranged by Dr. Clifford B. Connelley, Commissioner of the Department of Labor and Industry, Commonwealth of Pennsylvania, to be held at Harrisburg, Pa., Oct. 24 to 27.

This conference will include the features of the welfare and efficiency conferences and safety congresses of other years. The main topics to be discussed will include industrial waste, industrial co-operation, industrial publicity, industrial education, women and children in industry and the medical supervision of industry.

Prohibition Act Amendment Reported to Senate

The amendments to the national prohibition act which were passed by the House of Representatives June 27 were altered in some minor particulars by the Senate Committee on the Judiciary and were reported to the Senate on July 6. The presumed intent of the bill, as reported to the Senate, is satisfactory to the manufacturers of industrial alcohol, but it is believed that certain modifications will be necessary to make clear what is thought to be the purpose of the committee. As reported to the Senate, the paragraph of particular interest to the manufacturers of industrial alcohol reads as follows:

"If distilled spirits, upon which the internal revenue tax has not been paid, are lost by theft, accidental fire or other casualty while in possession of a common carrier subject to the transportation act of 1920 or the shipping act of 1920, or are lost by theft from a distillery or other bonded warehouse, and it shall be made to appear to the commissioner that such losses did not occur as the result of negligence, connivance, collusion or fraud on the part of the owner or person legally accountable for such distilled spirits, no tax shall be assessed or collected upon the distilled spirits so lost, nor shall any tax penalty be imposed or collected by reason of such loss, but the exemption from the tax and penalty shall only be allowed to the extent that the claimant is not indemnified against or recompensed for such loss. This provision shall apply to any claim for taxes or tax penalties not collected that may have accrued since the passage of the national prohibition act, or that may accrue hereafter."

The Senate committee in the first sentence added the words, "upon which the internal revenue tax has not been

paid." The common carrier was expanded so as to include a carrier by water. The committee in the last sentence added the words, "not collected." It is around this addition that some difference of opinion exists as to the meaning. After the word "warehouse" the bill as passed by the House contains this phrase: "and the person guilty of the theft has been convicted of the offense." That phrase was stricken out by the Senate committee.

Chemical Tonnage on Railroads

Chemicals and explosives furnished railroads of the country 17,336,161 tons of freight during the calendar year of 1920, according to the Interstate Commerce Commission's figures. Fertilizers furnished 13,976,256 tons of freight during the same period. Together these commodities furnished 1.39 per cent of the total tonnage carried by the railroads during the year. During the first quarter of 1921 chemicals and explosives furnished 1,337,246 tons of freight, while fertilizers furnished 2,142,552 tons.

Clay Products Work Begins

With the funds contributed by the associations of brick manufacturers to add to the money appropriated by Congress, the Bureau of Mines now has available approximately \$25,000 for work on heavy clay products. In addition, the Bureau of Standards has an appropriation of several thousand dollars which will be used on those phases of the work which fall within its field.

The first step being taken by the Bureau of Mines is to conduct an investigation as to the practice at a limited number of carefully chosen brick plants which are believed to be typical of many plants of the same character. A part of the work will be done at the University of Illinois. An effort will be made there to determine the maximum rate of vitrification and the maximum rate of water smoking.

Protest Against Duty on Jute

Members of Congress are receiving numerous protests against the duty on jute levied in the tariff bill. Jute fabric takes a duty of 1c. per lb. in the bill recommended by the committee. When the jute fabric is bleached, stenciled, colored or rendered non-flammable, an additional duty of 13 per cent ad valorem is levied. Bags or sacks made from plain woven fabrics of single jute yarns or from twilled or other fabrics composed wholly of jute are dutiable at 1c. per lb. plus 17 per cent ad valorem. Many of the protests are from fertilizer manufacturers who use jute bags for the distribution of their product.

"For the first time in history," says Representative Frear, of Wisconsin, one of the Republican members of the committee, "farmers will now pay for dutiable jute for the bags in which to ship grain. A non-competitive article thus enjoys the distinction of carrying a duty for revenue purposes only in a bill formulated to give protection to American interests, including the farmer."

Data Wanted on Glue and Gelatine

A monograph on "Glue and Gelatine" is being prepared by Jerome Alexander, one of the scientific and technologic monographs being issued under the auspices of the American Chemical Society and the Interallied Congress of Pure and Applied Chemistry. In order to round out his information on the subject, he would be glad to receive memoranda from men engaged in producing glue, gelatine, isinglass, or their substitutes, covering physical properties, chemical behavior, methods of manufacture, testing, and uses or specifications. Dr. Alexander's address for the summer is R.F.D. 4, Ridgefield Conn.

Lead Poisoning in the Pottery Trades

That workers engaged in certain branches of the pottery trade are seriously and constantly exposed to lead poisoning, chiefly from the lead contained in the glaze, and that this danger can be reduced, provided certain facilities and methods are altered by the pottery owners and certain precautions taken by the workers, sums up the findings of a report to the United States Public Health Service made by Consulting Hygienist Bernard J. Newman, Dr. William J. McConnell, Dr. O. M. Spencer and Statistician F. M. Phillips. This report is now in press.

The investigation, which was begun early in 1919, had been requested by the Brotherhood of Operative Potters because they desired to disprove the contentions that their trade was extremely hazardous and that the workmen in certain occupations were likely to develop lead poisoning. These contentions were maintained by life insurance companies as grounds for discrimination in the granting of life insurance policies to certain groups of pottery workers. The investigators received cordial support from both the workers and the pottery managers.

Ninety-two potteries, situated in New Jersey, Ohio, Pennsylvania and West Virginia, employing 21,000 persons, or 53 per cent of the total pottery workers in the United States, were investigated. Only the workers exposed to lead were examined, and of the total examined, 1,504 were males and 398 females.

LEAD RECEIVED THROUGH THE STOMACH

The portal of entrance through which the larger part of the lead is received by the body was found to be the stomach, as the lead was inhaled as dust, retained in the nasal and pharyngeal cavities and later swallowed with mucus, saliva and food. The chewing of tobacco, eating food contaminated with lead dust, and carelessness in personal habits such as wiping the lips, mustache, etc., with glaze-covered fingers, are contributory means toward the entrance of the lead into the human body.

A lesser, but still important portal of entry, is by the lungs, which absorb lead from fumes as well as dust. Absorption of lead through the skin is possible, but was found to be almost negligible in this case.

Risk of lead poisoning differs greatly in the many occupations of the pottery trade. The highest percentage of poisoning among men was found to be among the dippers and the next highest among the mixers and the odd-men. The highest percentage of poisoning among the women is among the dippers' helpers and the ware gatherers. These, among both men and women, are specified occupations, brought into direct contact with the glaze.

The percentage of lead poisoning for these, as well as for other workers, drops as the percentage of lead used in the glaze decreases and lead poisoning of course may be expected to disappear when leadless glaze is used. The adoption and use of leadless glazes is not impossible, for they are used now satisfactorily by European potteries. Certain objections, however, which have prevented their use in America, can at present be overcome only by radical changes in the manufacturing and firing methods. However, great improvements toward the decrease of lead poisoning can be brought about by the adoption of fritted lead glazes, as it would only be necessary to employ two or three men to prepare and frit the glaze against the present methods now employed, whereby large numbers come in contact with the lead glaze, either in its preparation or its use. Methods and formulas for making proper frits are given in the report.

The number of cases of poisoning found in the various occupations of the pottery trade does not alone establish their relative hazard, for this must be considered in the light of numerous modifying factors. The investigation, for instance, showed that the number of cases of lead poisoning increases with age of the workers, with their relative years of exposure and with the length of the work day. It showed also that poisoning is more prevalent among the men than among the women; but this was shown to be due to the fact that the men had been exposed for about three times as many years as the women. It

showed also that poisoning was more prevalent among workers who eat in the workroom or drink from vessels used in the workroom but not properly covered; and in plants where the toilet facilities, ventilation and lighting are bad, and in those where the dust counts and percentage of lead in the dust are high. It is easy to see that any or all of these respective factors are likely to be influenced by the susceptibility of the individual, or play a more or less important part in the production of lead poisoning as the personal habits and tendencies of the individual vary.

The relative weight to be given to these and other minor factors is very difficult to fix definitely, and the authors urge that no one should jump at the conclusion that to remedy any particular condition, other than remove the lead from the glaze, would immediately reduce poisoning.

RECOMMENDATIONS TO PLANT MANAGERS

It is recommended that plant managers should supply: Bubbling fountains with palatable drinking water; adequate dressing rooms with two-compartment lockers for each worker; decent and adequate toilet facilities; and adequate natural and artificial illumination and ventilation. They should discourage eating in the workroom and eating anywhere without previous washing of the hands and face; should encourage the use of overalls; should absolutely forbid dry sweeping and all sweeping of any type during work hours; and should prevent, so far as possible, the spilling of glaze and the consequent dust and dirt.

American Valuation Association

The American Valuation Association was formed by a gathering of representative American manufacturers at the Chemists' Club, in New York City, June 16. Walter Camp, president of the New Haven Clock Co., was chosen president of the association at that time. Other officers are: D. W. Jayne, of The Barrett Co., vice-president; Stanley Williamson, of the Linde Air Products Co., secretary, and F. D. Dodge, of the Toy Manufacturers of the U. S. A., treasurer.

The executive committee includes William Burgess, of the U. S. Potters' Association; Walter Camp; George Chatillon, of John Chatillon & Sons; F. D. Dodge; Clement J. Driscoll, of the Liberty Lace & Netting Works; D. W. Jayne; H. J. Strugnell, of the Remington Arms Co., Stanley Williamson, and J. F. Zoller of the General Electric Co. Mr. Zoller is also chairman of the membership committee, and Mr. Driscoll is chairman of the publicity committee.

It is the purpose of the new association, as announced by the executive committee, to take up every phase of the valuation of imported merchandise and to submit to manufacturers a statement regarding the advantages to be derived by American industry through adopting the American rather than the foreign valuation plan.

Summer Pulp and Paper Course at University of Maine

In order to make full use of its facilities for training technical men for the pulp and paper industry, the University of Maine has instituted a pulp and paper summer school which opened on June 27 with a good-sized class. The courses in pulp and paper chemistry and technology will continue until Aug. 5. They include: Laboratory and small-scale experiments on soda pulp and sulphite pulp, pulp bleaching, paper testing and analysis; general lectures on raw materials of present or probable future use, modern pulp and paper making, costs, use of libraries, visits to mills.

C.W.S. Moves Offices

The headquarters of the Chemical Warfare Service in Washington has been moved from 1800 Virginia Ave. to the seventh wing of the Munitions Building. General Fries' office is No. 1062. Under the new arrangement the entire service is housed compactly in much better offices than those occupied by the service in one of the temporary buildings.

Plans for Fall Meetings of Chemical Societies

Departing from its usual custom, the society of Chemical Industry will hold its annual meeting on this side of the Atlantic. The members will join with the Canadian branch of their organization in sessions in Montreal late in August. Their official hotel quarters will be the Windsor Hotel, while the scientific and business sessions will center at McGill University, where there will be a special convocation. The Canadian and British chemists will then inspect numerous plants and on Thursday, Sept. 1, will visit Grand Mère and Shawinigan Falls industries under the auspices of the Shawinigan Falls section of the society. The delegates will then proceed to Ottawa and Toronto, where they will be entertained by the local sections. On Monday, Sept. 5, they will reach Niagara Falls, where they will view the vast establishments which modern chemistry has created.

On the afternoon of Labor Day the members will cross the border into this country. They will be met by a committee of the American section of their society and conducted through the industrial plants on this side of the Falls. Dinner will be served at Buffalo, after which the visitors and their hosts will leave on a special train east. On their arrival next morning (Sept. 6) at Syracuse they will have luncheon with the Solvay Process Co. and make a tour of the large factory of this corporation. The chemists will then go to Albany and from there take the night boat down the Hudson River to New York City.

The visitors will be welcomed next day by members of the American Section of the Society of Chemical Industry, who will be their hosts at a luncheon. Elaborate arrangements for the reception of the chemists of all three nationalities will be carried out, as now being planned by the various societies, through the co-ordinating committee, of which Dr. B. C. Hesse is chairman and Dr. Allen Rogers is secretary. The festivities, meetings and entertainments which will follow are designed to bring into closer bonds all chemists of Anglo-Saxon stock.

The fall meeting of the American Chemical Society is to be held in New York City Sept. 6 to 10, inclusive. The first contact between the visiting members of the two great organizations which represent chemistry in three lands will be at a lawn party to be given on the afternoon of Sept. 7 to foreign guests and to scientific societies at Columbia University. Other societies asked to participate in the welcoming of the visitors from abroad are: The American Electrochemical Society, the American Institute of Chemical Engineers, the American Section of the Société de Chimie Industrielle and the Manufacturing Chemists Association of the United States. All the foreign guests have also been invited to the smoker and entertainment of the American Chemical Society, which will be held on the evening of Wednesday, Sept. 7.

Scientific sessions of the American Chemical Society are to be held at Columbia University, its official headquarters. To all these meetings the British and Canadian guests have been bidden. They will also be present at the banquet of the American Chemical Society on the evening of Sept. 9 at its hotel headquarters, the Waldorf-Astoria.

An interlude devoted to social activity on Sept. 10, with plenty of golf and tea, and on the 11th to a boat excursion will fill in the time before the next event.

The National Exposition of Chemical Industries, which is to be held during the week of Sept. 12, will constitute a most appropriate sequel to the international gathering of chemists. Here under one roof the visiting chemists will find every type of apparatus used in American chemical plants as well as a wide variety of the products of the chemical industries—all conveniently arranged for study and inspection.

Civil Service Examination

Vacancies for assistant metallurgical chemists at the Naval Ordnance Plant, South Charleston, W. Va., at \$5.44 per day, will be filled from an open competitive examination to be held Aug. 17.

Applicants should apply at once for form 1312 to the Civil Service Commission, Washington, D. C.

Book Reviews

RUBBER MANUFACTURE. By *H. E. Simmons*, professor of chemistry, University of Akron, Ohio. New York: D. Van Nostrand Co. 150 pp., illustrated. Price \$4.50.

This book deals in a rather general way with the problems of the rubber industry, and apparently has for its object the enlightenment of young compounders who have to deal with the difficulties of so-called "service work." This class of compounders is not as a rule very well grounded in "theory" but is usually well up on the "practice" of keeping the factory going. These compounders will agree to find a substitute for everything used in the factories with the single exception of sulphur. The conception of the type of man this book is intended for is of prime importance.

The writer feels that as a whole the work has been reasonably well done. Here and there are chapters which are exceptionally good, as for example the one on physical testing. From the service man's point of view it is excellent. But all too frequently glaring errors occur, and other evidences of lack of thorough digestion of the matter in question. In addition there are several mistakes which should have been caught by the proofreader. Also terms are used which have not been previously described or otherwise defined. In view of the fact that many of the readers will be young rubber chemists, this is very regrettable. With this in mind the writer will attempt in reviewing the various chapters to correct a few of the errors which appear most glaring.

Chapter I—The History of Caoutchouc, in which the historical features are well covered.

Chapter II—Rubber in the Amazon Basin, in which the South American rubbers are described in sufficient detail for the average compounder. The explanation of the excellence of fine para rubber being due to carbon from the smoke of the *uricuri* palm nut is, to say the least, rather novel.

Chapters III and IV.—These describe the rubbers of Africa and Central America respectively. In speaking of the harvesting of guayule the author mentions that the rubber is extracted from the ground shrub by means of naphtha, which is then partly distilled, after which alkali is added. This, he says, holds the resins in solution and the rubber separates out. This is also rather novel.

Chapter V.—Rubber plantation practice is described. It is rather good, though not quite exact as to modern methods. It is customary on the best plantations to dilute the latex to constant rubber content and then to add a definite amount of dilute acetic acid.

Chapter VI.—A discussion of colloids and colloidal principles is contained in this chapter. The subject matter is aptly chosen and the presentation is particularly good.

Chapter VII.—This chapter is an attempt to apply the principles of colloidal chemistry to problems met in coagulation and other phases of the industry. It must be observed that the writer continually confuses lampblack with gas or carbon black. It is the latter and not lampblack which imparts such desirable properties to rubber.

Chapter VIII.—This contains a very much condensed review of the work of Eaton, Grantham and others on different means of coagulation and variability. Unfortunately, the subject is somewhat too broad for so much "boiling down." However, the chapter is particularly good and were it not marred by the use of technical terms without explanation and the discussion of subjects such as "Byrne cure" without description it would be excellent.

Chapter IX.—This chapter on the theory of the constitution of rubber is good and sufficient for the purpose intended.

Chapter X.—This discusses synthetic rubber. The author makes the very apt comment that we might as well attempt to produce synthetic apples. Rubber is a vegetable product and as such can be grown in sufficient quantity to meet the demand.

Chapter XI.—Methods for testing crude rubber are described. It might be observed that most rubber companies have become very careless in this respect. Rubber is bought at the various auctions almost solely on appearance and the reputation of the estate producing it. The wide use of organic accelerators has eliminated the difficulties due to "variability"—i. e., the variation in time of cure when mixed with sulphur alone.

Chapter XII.—The manufacture and use of inorganic fillers are discussed. The subject matter included has not been well chosen or well arranged, and in a few instances is erroneous. For example, the toughening effect of zinc oxide and gas black are not mentioned. One would imagine that the chief use of zinc oxide is as a white pigment, while as a matter of fact about 90 per cent of that consumed contains a little lead and therefore gives the stock a slight yellow cast. Lithopone is a better white pigment than zinc oxide. Red lead passed out of use about five years ago. Many specifications exclude it, and because of its strong oxidizing tendencies most compounders would not use it under any conditions. Under lime the author fails to differentiate between hypothesis and fact in discussing the ability of lime to take up moisture and prevent blowing in stocks. Under barytes, the brown color of "off color" material is due to iron.

Aluminum oxide made through the sodium aluminate route is not "coming into use in some factories," due to the alkali which it contains and which is almost if not completely impossible to extract.

Under the caption of fillers the author has neglected glue, which is now widely employed.

In discussing the production of zinc oxide it will be noted that the author did not avail himself of the services of the New Jersey Zinc Co. Research Laboratories, otherwise he would not have overlooked the decided advantages of this material and his description of the process of manufacture would have been more to the point.

Under antimony, the reviewer ventures to suggest that crimson antimony is usually oxysulphide and not trisulphide. Also "stibnite" is the mineral employed, not "sribnite."

It might also be observed that the manufacturer's explanation of the merits of an antimony tube are highly interesting but not very instructive.

Many of our most satisfactory pigments are lakes.

Lampblack is not a toughener and is not extensively used in tire stocks, but gas black is.

Graphite due to its coarse particles has no stiffening effect.

Chapter XIII.—The manufacture and use of organic accelerators are discussed. Of the common accelerators he mentions: aldehyde ammonia, paranitrosodimethylaniline, paraphenylenediamine, hexamethylenetetramine, thiocarbanilide, aniline. He fails to mention: triphenyl guanidine, diphenyl guanidine, formaldehyde aniline, the CS₂ reaction products with dimethylamine and piperidine. Nothing is said regarding the proper proportions of any accelerator. He makes the highly interesting observation that aldehyde ammonia is produced by passing dry ammonia gas into a solution of formalin. This would give hexamethylenetetramine. He should have said "acetaldehyde."

Chapter XIV.—The manufacture and use of rubber substitutes are rather well described. Mineral rubber (MR) deserves more treatment than it received.

Chapter XV.—This chapter contains a description of the theories of vulcanization. Except for poor proofreading it is well done. For example the following reaction is given without explanation of its terms:

The term NS₂ is rather misleading; certainly there is no combination of nitrogen and sulphur like that. The author might have mentioned *n* mols of C₁₀H₁₀ plus *N* mols of S₂, which would certainly have made the passage more clear.

It should be noted that the addition of sulphur to rubber increases with the time of heating, which is contrary to our usual experience with chemical reactions.

Chapter XVI.—This describes "Reclaiming" and is very

good, except for the fact that the Mark's process, which is most generally employed, is not sufficiently emphasized.

Chapter XVII.—The preparation of crude rubber for compounding and manufacturing is recounted.

Chapter XVIII.—The principles of compounding are discussed. From the service man's viewpoint the work is excellent.

Chapter XIX.—Several of the author's methods for analyzing manufactured rubber are described. Chloroform is used rather extensively in place of the carbon bisulphide specified. The Watters and Tuttle method for total sulphur, which is now in almost general use, is not mentioned.

Chapter XX.—This chapter, on Physical Testing, is very good. An illustration of a plastometer is included without mention or description in the text.

Chapter XXI.—The work which Prof. Simmons is undertaking in Akron in the way of establishing a reputable course in rubber chemistry is described. His effort is good and he deserves the support of all American rubber companies and the Rubber Association.

ANDREW H. KING.

Personal

C. L. BACHELDER, who has been assistant in the pulp and paper section of the Forest Products Laboratory, has resigned, and is now with the Consolidated Water Power & Paper Co., Appleton, Wis., under Dr. Otto Kress.

H. H. BARKER, formerly chief chemist and plant manager of the Ore Products Corporation, Denver, Col., is now chief chemist of Corning & Co., Albany, N. Y.

ALFRED T. CHILD, for the past two years associate professor of chemistry at Rose Polytechnic Institute, Terre Haute, Ind., will spend the summer at Stamford, Conn. He plans to visit industrial plants.

VANCE P. EDWARDES, who has been with the Forest Products Laboratory for the past three years, is now with the Interlake Pulp & Paper Co., Appleton, Wis., in the sulphite department.

REIMAN G. ERWIN, formerly with the Roessler & Hasslacher Chemical Co., St. Albans, W. Va., is now chemical engineer with the Celluloid Co., Newark, N. J.

CHARLES H. MACDOWELL, president of the Armour Fertilizer Works, was re-elected president of the National Fertilizer Association at the recent annual convention held at White Sulphur Springs, W. Va. This is Mr. MacDowell's fourth term as president of the association, he having been previously elected to that office in 1903 and 1904 and again in 1920.

JOHN J. MULLIGAN, who was formerly plant metallurgist for the U. S. S. Lead Refinery, Inc., East Chicago, Ind., is now assistant superintendent for the same company.

DR. HENRY P. TALBOT has been appointed acting dean of Massachusetts Institute of Technology to succeed Dr. A. E. Burton, who recently resigned. Dr. Talbot is chairman of the faculty, and will also retain the directorship of the department of chemistry.

ARTHUR L. WALKER, professor of metallurgy at the Columbia School of Mines, has gone to Europe for the vacation months.

The Society for the Promotion of Engineering Education has elected the following officers for the ensuing year: President, Charles F. Scott, Yale University; vice-presidents, H. J. Hughes, Harvard University, and E. J. McCaustland, University of Missouri; secretary, F. L. Bishop, University of Pittsburgh; treasurer, W. O. Wiley, New York City. The following are members of the Council: P. H. Daggett, University of North Carolina; J. H. Dunlap, University of Iowa; M. L. Enger, University of Illinois; J. C. L. Fish, Leland Stanford University; F. E. Gieseke, University of Texas; Morris Knowles, Pittsburgh, Pa., and O. M. Leland, University of Minnesota.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, July 11, 1921.

Trading of a desultory character has featured the chemical market during the past week and there has been little in the way of price changes uncovered. A fair amount of miscellaneous inquiries was received, but these did not result in any large lot transactions and most of the business placed has been in small lots representing the actual wants of the consuming trade. The holiday exerted its usual quieting influence and the close of the week found business dormant in most local directions.

The first draft of the new tariff bill is now under discussion and the trade can draw its own conclusions from what Mr. Fordney thinks about the import duty as a protection to the American chemical industry. Importations of German chemicals are increasing and may be expected to increase until the new tariff bill becomes a law, the time being purely problematical. Meanwhile some relatively low prices are being named on chemicals which forecast dullness for American goods.

Among chemicals which have shown some activity are soda ash, caustic soda, bichromate, prussiate and nitrite of soda. The first two have shown considerable steadiness. Bleaching powder has sold more freely and the outlook has improved for business in this chemical through the recent settlement of the labor strike at paper mills in this country and Canada. Bleach showed a better tone at the close with some sellers a little higher in their views. Among the smaller items citric acid has ruled about steady. Imported tartaric acid has not declined any further regardless of a lowering in the price of domestic producers. Formaldehyde showed some irregularity in second hands. Camphor has been in fair request at steady prices all around. In general, it can be stated that quite a few can see no prospects of material improvement in trade conditions during July and August, but early in September it is expected that the beginning of a general recovery will become pronounced. For more than six months manufacturers and others have been engaged in working off high-cost inventories. This has been largely at the expense of earnings. It has added to the feeling of depression that has prevailed and probably in many instances has made the situation appear to be much worse than it is in reality. Consumers are uncertain as to future prices and having been taught a severe lesson because of overexpansion in the inflation period, are now exceedingly careful and will not take the chance of laying in supplies at what might be considered high prices later on. The country has gone from one extreme to another and that there will be a rebound is an inevitable conclusion.

GENERAL CHEMICALS

Spot *caustic soda* is being held steady at \$4.10 per 100 lb. for standard brands, and moderate trading was reported at this price. It is stated that miscellaneous inquiries are reaching the market in fair volume and that business in the aggregate is quite satisfactory. Resale offerings are not heavy and some sellers showed a disposition to advance their views. Producers are maintaining the contract price of 3½c. per lb., basis 60 per cent, f.o.b. works.

Producers report a quiet trading in *fluoride of soda* and state that small sales are going through on the basis of 12c. per lb. Buyers seem to be fairly well supplied with this material and are content to operate in small quantities. Prices on spot *nitrite of soda* are heard all the way from 7¼@8c. per lb., depending entirely upon the seller. Scattered transactions were reported at 7½c. per lb. As stated previously, stocks of this chemical appear to be well held in most directions and there continues to be a

feeling that the market would respond to any buying movement. Spot *bichromate of potash* is generally quoted at 11¾@12c. per lb., but odd lot sales have been made below this price and in one direction it was stated that 11c. could be done. Activity has continued along narrow lines and the desire to secure new business in the face of a quiet demand has kept the market somewhat irregular.

Dealers in *caustic potash* quote the 88-92 per cent at 5@5½c. per lb., and in some quarters it was intimated that the inside price might be shaded on a firm offer. Rumors were heard that a few small lots have changed hands down to 4¾c. per lb., but this figure did not represent the actual market, according to sellers. Standard *bichromate of soda* was quoted at 8¼@8½c. per lb. Scattered transactions were noted at 8½c. but the market appeared quiet in most directions, with offerings relatively small among second hands. Imported *prussiate of soda* was quoted at 12½@12¾c. per lb., according to seller. Odd lots might have been purchased at slight concessions, but the market in general looked somewhat steadier than it did at the close of the previous week. Resale *soda ash* in single bags sold at \$2.10 per 100 lb. and upward, according to quantity. Barrels were in fair request, with small lot sales noted up to \$2.60 per 100 lb., while 2½c. per lb. was named in some quarters for carlots. No change in prices was heard at the works, and sellers named \$1.60 per 100 lb. for single bags basis 48 per cent. Prices are a shade easier on formaldehyde with prominent sellers offering as low as 13¼c. per lb. for immediate shipment. Odd lot sales have been made by dealers down to 13c. and the extreme range is 13@14c. per lb., depending upon seller, brand and quantity. Trading in *oxalic acid* is taking at 17½@18c. per lb. on spot. Some sellers are asking above 18c. for domestic material and this variety is governed entirely by the views of the individual seller at present. The minimum price quoted is for imported stock.

COAL-TAR PRODUCTS

Trading in the coal-tar products market during the past week has shown no particular change from that of previous reports, which were of a somewhat improved tone with inquiries coming from a broader field and concerning a larger variety of products. The amounts involved in transactions were confined to small quantities for use at the moment and nothing in the nature of contract business was developed. There was not much activity in the crude market outside of *benzene*. The demand for both the pure and the 90 per cent is steady and prices are firm. Supplies of *naphthalene* are plentiful and with the lack of demand prices depend upon the seller, with some quoting as low as 7c. per lb. and others steady in their views at 8½c. per lb. for flakes. The tone in the market for *phenol* is improving and some sellers report a more active tendency among buyers. There is very little business being done below 10c. per lb., while the range was up to 15c. per lb., depending on quantity. Intermediates were steady in tone and small lots continued to move in a routine manner. A fair demand was reported for *phthalic anhydride* and prices were steady at 45@50c. per lb. *Aniline oil* was dull and prices remained practically unchanged. *Beta naphthol* was somewhat lower at 35@38c. per lb., with trading reported quiet. Consumers of *aniline oil* are interested only in supplies sufficient for the moment and so far this week no large sales were reported. Prices, however, remained steady at 20@26c. per lb., depending upon quantity and seller.

There was very little activity noticeable in any quarter of the market on *dimethylaniline*. Prices varied somewhat depending on seller with a range from 40@50c. per lb. The tendency of the demand for *beta naphthol* has seemed to fall off and while factors in some quarters are fairly steady in their quotations, sellers in some quarters will shade on a firm order so that 35c. per lb. has been possible. Factors state there is very little change taking place in the situation on *alpha-naphthylamine* and very little interest is shown on the part of consumers. Prices are held on the recently quoted basis of 35@40c. per lb. The market on *paranitraniline* shows few signs of any

broadening and only a moderate routine business is passing, while prices depend on seller, with 85c. per lb. heard in some quarters. A firm order for round lots might bring shading. Factors continue to report a fairly steady consuming demand for moderate quantities of *para phenylenediamine*. The market is in a fair condition on supplies, with prices ranging from \$1.75@ \$2 per lb., depending on quantity.

MISCELLANEOUS MATERIALS

Interest in the market for miscellaneous materials centered in the publication of details on the Fordney tariff bill. The bill as presented to the House of Representatives provides for higher duties on *barytes* and *zinc oxide*. The measure provides for a duty of \$4 per ton on crude *barytes* and \$7.50 per ton on the manufactured. The market held at \$36@ \$42 per ton on prime material and \$26@ \$28 per ton on off colored. Prices on *blanc fixe* ruled steady, but closed unchanged at 4½c. per lb. in carlots and 4½c. per lb. for less than carlots. There was a fair inquiry noted for this material. Interest in *zinc oxide* centered around the announcement made by leading producers of a general reduction in prices. The decline amounts to 1½c. per lb. on the lead-free and French process *zincs*. Lead-free closed at 7½c. per lb. carlots, with the 5 per cent at 7½c. and the 10@35 per cent at 7c. per lb. French process, red seal, closed at 8½c., carlot basis, with the green seal at 9½c. per lb. and the white seal at 11c. The XX variety was quoted at 7½c. per lb.

VEGETABLE OILS

Spot prices for *chinawood oil*, so far as importers were concerned, held around 15c. per lb., but resale material was available here and there at concessions. Futures were neglected, but held nominally at 10½@10¾c. per lb., hardwood barrels included, c.i.f. N. Y. The feature of the market on *coconut oil* was the sale of several large parcels of copra at comparatively steady prices. One lot of 900 tons of Java copra sold at \$4.95 per 100 lb., July shipment. Another lot sold at 5c. per lb. c.i.f. N. Y. The domestic oil trade was not very active with prices more or less nominal. There were sellers of domestic Ceylon type oil at 8½c. per lb., sellers' tanks, N. Y. On the coast 8½c. was bid for snowflake oil, immediate shipment, but no sales were recorded. Outside lots of Manila oil for immediate shipment were offered at 8½c. lb. bulk basis, c.i.f. N. Y. with intimations that that figure might be shaded on a firm bid. Cochin style oil held at 11@11½c. per lb. on spot. Owing to the strength in cottonseed oil and other competing oils sellers in the West were not free in offering crude *corn oil* and in some directions 6c. per lb. was regarded as an inside figure, tank car basis, f.o.b. Chicago. There was a good inquiry for domestic crude *peanut oil*, and sales were noted in the past few days at prices ranging from 6¼@6½c. per lb., tank cars, f.o.b. mills, southeast. The sale at the outside figure was noted during the week. The market was firm reflecting the uplift in crude cottonseed, which actually sold at 6½c. per lb. f.o.b. Texas.

The St. Louis Market

ST. LOUIS, Mo., July 8, 1921.

Business in the general list of drugs and fine chemicals continues to increase, with large and frequent inquiries and in most cases, resulting in business. The demand for heavy chemicals has been considerably lighter in the past two weeks, as the market for the most part remains unchanged. The prediction of two weeks ago has apparently been justified—i.e., that the second-hand stocks are about depleted and that the buyer can again safely take the manufacturer's schedule as indicative of the real market price. The market in the past on many chemicals was weakened owing to the severe foreign competition, but since the introduction of the proposed tariff bill made public during the last week, the market is again assuming a firm position and many commodities are stiffening.

ALKALIS

Caustic soda demand has been very poor, with manufacturer's schedule prevailing. The demand for *soda ash* is very light, with the price in round lots holding at \$2.95@

\$3.25 per 100 lb., basis 58 per cent light. *Bicarbonate of soda* and *sal soda* have a demand much under routine, with prices remaining the same.

INDUSTRIAL CHEMICALS

Carbon bisulphide is one of the very active items at the present moment, with many inquiries resulting in business. The demand for *hyposulphite of soda* continues to be steady and is moving through regular channels. Sulphur remains at \$2 per 100 lb. for the commercial, with demand a trifle light within the previous two weeks. A few sales have been reported below cost in an effort to move heavy stocks of this item.

DRUGS AND PHARMACEUTICALS

Acetanilide continues to be quiet. *Acetphenetidine* is not moving as rapidly as might be expected, inquiries being small and few. The *bromide* situation has undergone no material change. Foreign importations continue to be noted and supplies are liberal. *Caffeine* is in fair demand with no change in price. *Carbon tetrachloride* has been in a fair demand, with a price at 12c. per lb. in 100-gal. drums. The status of *chloral hydrate* has had no change, with a normal demand from regular sources. *Cream of tartar* continued to maintain its present schedule with a limited demand. There is a decided improvement in the demand for *glycerophosphates* and a very substantial amount of business is passing. *Hydrogen peroxide* continues to move very briskly. Some of the *hypophosphite salts* are showing an increase. *Iodides* have shown a fair increase and manufacturers hope this condition will continue with the present price reduction brought about by the keen competition of second hands. *Mercurials* have shown no improvement since last report. *Phenolphthalein* continues to move in a routine way with a slight improvement in inquiries. *Rochelle salt* and *seidlitz mixture* are lacking interest since the recent reduction in price. The second-hand lots of *saccharine* are still a disturbing factor to the market and until these goods are disposed of factors do not look for any improvement. A routine business of *salicylates* is being enjoyed. *Sodium benzoate* remains easy and the demand is rather light. Competition in this commodity does not seem to be as sharp as it was recently. The hot weather which has been experienced lately has had a good effect on *zinc stearate*, which is now moving in large volume and jobbers should carry liberal stocks. *Glycerine* again declined to 15½c. per lb. spot, with contracts offered at 16c. Most of the six months' contracts were signed at the latter figure.

ACIDS

The position of heavy acids has not made any material change. However, a fair improvement has been noted with no change in price. Factors are still disappointed in the *citric acid* situation. The demand is a trifle better, but soft drink manufacturers are still averse to anticipating and purchasing larger quantities. The movement into consuming channels is also below normal. The activity in *pyrogallie acid*, both *resublimed* and *crystals*, remains since last report and some very nice business is being transacted. Some very large inquiries have been received for *succinic acid*, and in most cases business has resulted. Since the reduction in price recently announced by manufacturers, there has been nothing of importance developed in the *tar-taric acid* situation.

VEGETABLE OILS

Linseed oil has declined slowly the past two weeks and now holds at 75c. per gal. in cooperage, with little contracting. *Castor oil* still holds at 10½c., with only a fair demand. *Turpentine* has likewise been affected by the slowup of the paint industry and is offered at 57c. per gal. in 5-bbl. lots.

PAINT MATERIALS

The paint industry is experiencing the dulllest season in years, and as a consequence the demand for *barytes* and *lithopone* has been exceedingly light. Though prices remain the same, shading is to be expected when there is any amount of business in sight.

The Iron and Steel Market

PITTSBURGH, July 8, 1921.

Last week it was common talk in the steel trade that formal price reductions would be announced this week, probably on Tuesday. On Monday night the Bethlehem Steel Co. gave to the Associated Press a statement that it was reducing its regular prices by certain amounts. Other independents promptly "recognized" the new prices and on Wednesday night the United States Steel Corporation made an announcement that it had reduced its prices correspondingly.

At the middle of April a uniform market was developed, by the independents making some advances from their former cut prices while the Steel Corporation reduced its prices. Since then there had been a plain decline of \$5 a net ton in wire products and in sheets. In other products the April prices were nominally though in most cases not actually the market.

The prices thus announced are: Billets, \$33; slabs, \$34; sheet bars and small billets, \$35; bars, 1.90c.; shapes and plates, 2c.; blue annealed sheets, 2.65c.; black sheets, 3.50c.; galvanized sheets, 4.50c. Tin plate is \$5.75 per base box. It had been \$6.25 by the April schedule, while there had been shading to \$5.75 or less on stock plate but little shading on plates ordered for production.

The new prices are the market on sheets, and probably the market on bars. On plates prices of 1.90c. and less had already been named quite freely and it is quite improbable that the market will advance to a 2c. level.

New prices for pipe, hoops and some other commodities are still to be announced. The April price on hoops had been 2.75c., but 2.50c. has frequently been done in the past two or three weeks.

The season cotton tie price has been announced, \$1.35 per bundle, weighing 45 lb. This compares with \$2 in 1920, \$1.70 in 1919, \$2.10 in 1918 and 1917 and an average of 79½c. in the ten years 1904 to 1913 inclusive.

TRADE AWAITING "FINAL" REDUCTION

For months past the trade has been looking forward to the time, indefinitely in the future, when the steel market would experience a sort of "final" decline—i. e., a decline that would occur when buyers became ready to take hold in something like a free way and there would be an incentive to the mills to make prices that would induce the placing of business. The declines to date have not been of that character, since they have not perceptibly increased the volume of business, and they have occurred simply through mills competing with one another for the limited quantity of business that was going to be placed anyhow. There is no sign yet of the time when a buying movement can be started. Consumers are still engaged in liquidating stocks of steel and of their products made from steel, and they do not seem to be making very rapid progress.

The condition, of course, is that the production and shipments of steel by the mills is well below the rate of actual consumption, or wearing out, or putting into employment, of steel. The movement in steel is far below a relation to the volume of business activity generally, even though general business is relatively quiet. It is rather startling to observe that debits to individual accounts at banks as reported by the Federal Reserve Board and which the board says "are indicators of the volume of the nation's business" were only 19 per cent less in the five weeks ended May 25 than in the same period of 1920, whereas the production of steel is barely 25 per cent of the rate of a year ago.

PRODUCTION OF STEEL AND PIG IRON

Production of steel ingots is now at about 10,000,000 gross tons a year, or at a shade under 20 per cent of capacity, the Steel Corporation operating at above that rate and the independents at below it, some independent mills being entirely closed. Pig-iron production is at the rate of about 11,000,000 tons.

Pig iron prices continue to soften, prices being off 50c. in the week, with bessemer at \$22, basic at \$20 and foundry at \$21, valley furnaces. Connellsville coke is a shade stronger, being rather firm at \$3.

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

GADSDEN—The Etowah Health Chemical Co. has acquired a local building and will establish a new plant for the manufacture of sweeping compounds and kindred products.

Arkansas

EL DORADO—The El Dorado Refining Co., recently incorporated, has preliminary plans under way for the erection of a new oil refinery. The initial works will comprise two units, each with daily output of about 1,000 bbl. It is proposed to increase this production to about 5,000 bbl. per day at a later date.

SPRINGDALE—The Welch Grape Juice Co., home office, Westfield, N. Y., plans the erection of a large plant here, for the manufacture of grape juice from the product of the vineyards in the Ozark regions of Arkansas. W. A. Ragland, McCall Bldg., Memphis, Tenn., will have direction of this work.

California

SAN FRANCISCO—The W. K. Minerals Co., San Francisco, has acquired the property and business of the Magnesia Products Co., with mineral lands near Patterson, Stanislaus Co. The new owner is said to be planning for extensive operations at the property for the manufacture of magnesia products.

Delaware

WILMINGTON—The blending house at the plant of the United States Flashless Powder Co., Carrerott, near Wilmington, was damaged by fire, caused by an explosion, June 30. An official estimate of the loss has not been made.

WILMINGTON—The Darco Corporation, du Pont Bldg., a subsidiary of the Atlas Powder Co., is said to be selecting a site in Louisiana, in the vicinity of Houma, for the erection of its proposed new carbon-refining works, estimated to cost about \$1,000,000 with machinery. The carbon will be produced from lignite beds in this section. W. J. Webster, head of the Atlas company, is president of the Darco Corporation; H. B. Walmsley is vice-president and secretary.

Illinois

BLUE ISLAND—The American Wire Fabrics Co., 136th St. and Western Ave., is taking bids for the erection of a new 1-story galvanizing plant at its works, 47 x 145 ft. A warehouse building will also be constructed and both structures are estimated to cost about \$100,000. Headquarters of the company are at 208 South La Salle St., Chicago.

CHICAGO—LaSalle Extension University is planning the erection of a \$500,000 building at the southeast corner of Michigan Ave. and 41st St. Architect's plans call for a 6-story reinforced-concrete structure with white terra cotta exterior.

Indiana

COLUMBUS—The Indiana Oil Refining Co. will commence the immediate erection of the superstructures for the different buildings at its new refining plant, located on a site about three miles from the city. Foundation work has been completed. The new refinery is estimated to cost about \$500,000 with machinery. O. L. Bartlett is president.

Iowa

DES MOINES—The Keith Furnace Co., West 11th St., manufacturer of furnaces, etc., is taking bids for the erection of a new 1- and 2-story plant at East 26th St. and Bran Ave., estimated to cost about \$250,000 with equipment. Boyd & Moore, 314 Security Bldg., Des Moines, are architects.

Kentucky

ASHLAND—The Mayo Oil Service Co., 11th and Front Sts., recently incorporated, is planning for the erection of a new oil refinery on a local site. John C. C. Mayo is president and treasurer.

Louisiana

SHREVEPORT—The Henderson Cotton Oil Co. is reported to be planning for the rebuilding of the portion of its plant, destroyed by fire, June 22, with loss estimated at about \$300,000, including equipment.

Maryland

BALTIMORE—The Gwynns Falls Paper Co., 517 Calvert Bldg., has completed plans for its proposed new plant at Gwynns Falls and will begin construction during the present month. The plant will be devoted to the manufacture of high-grade paper board products and will be equipped for a maximum daily output of about 85 tons of material. It will give employment to about 150 operatives and is estimated to cost in excess of \$500,000. Joseph H. Wallace & Co., 5 Beekman St., New York, are engineers. Joseph G. Mayo, formerly connected with the Spanish River Pulp & Paper Mills, Canada, will be manager at the plant. George W. Davis is head.

BALTIMORE—The Holdtite Rubber Co., 919 Baltimore St., has foundations under way for the erection of its proposed new plant at Warner and Ostend Sts., for the manufacture of rubber specialties. It will be 1-story, 50 x 125 ft., and estimated to cost about \$25,000.

Michigan

DETROIT—The Solvay Process Co., Syracuse, N. Y., has arranged for the curtailment of operations at its local plant for an indefinite period.

Missouri

ST. LOUIS—The Wrought Iron Range Co., 5661 Natural Bridge Ave., has filed plans for the erection of its proposed new 2-story plant addition, 146 x 220 ft., estimated to cost about \$75,000. The Murch Bros. Construction Co., Railway Exchange Bldg., is contractor.

KANSAS CITY—The new chemical laboratory now being erected at 729 Holmes St. by A. W. Estabrook is nearing completion and will be equipped and placed in operation at an early date. The structure is 2-story and basement, 40 x 60 ft.

New Jersey

LAKEHURST—The War Department is arranging for the abandonment of the property occupied here by the chemical warfare plant, and plans are being perfected for the removal of this work to the Edgewood Arsenal, Maryland. The local site is about 18,000 acres and will be placed on the market.

JERSEY CITY—Colgate & Co., 105 Hudson St., are said to have plans under way for the remodeling and improving of the state reformatory buildings at Jeffersonville, Ind., recently acquired for the establishment of a new branch plant for the manufacture of soaps, powders and kindred specialties. With new structures, the work is estimated to cost about \$500,000.

MILLVILLE—The Whitall Tatum Co. has blown out two of its local glass manufacturing plants for the summer season. The glass works at South Millville will be continued in service for several weeks.

New York

SYRACUSE—The Onondaga Pottery Co., 1858 West Fayette St., manufacturer of earthenware products, is completing plans for the erection of a new plant on Court St., estimated to cost about \$500,000 with machinery. No date has as yet been set for asking bids, or time decided for erection of the structure. Guy L. Noble, Union Bldg., is engineer.

MELLENVILLE—The Columbia Valley Paper Co., 44 Howard St., Albany, N. Y.,

has completed plans for the erection of a new paper mill at Mellenville. Construction will be commenced at an early date. F. B. Oldham is president.

ALBANY—The Hires-Turner Glass Co., 30th and Walnut Sts., Philadelphia, Pa., has awarded a contract to the Panzieri-Hogan Co., 90 State St., Albany, for the erection of its proposed new local plant on Tivoli St., comprising main glass manufacturing building and boiler plant, estimated to cost about \$100,000.

North Carolina

MIDVALE—The Canton Brick & Fireproofing Co., Canton, N. C., is planning for the construction of a new plant at Midvale for the manufacture of brick and other burned clay products.

Ohio

STEUBENVILLE—The Wheeling Steel Corporation, Wheeling, W. Va., has preliminary plans under way for extensions and improvements at its La Belle Iron Works, Steubenville, to cost in excess of \$2,000,000. It is said that the company proposes to develop this plant as its leading producing unit.

SANDUSKY—The Hord Color Products Co. has completed the erection of its new plant, to replace the works destroyed by fire last fall, and operations have been started.

Oklahoma

ENID—The Garfield Refining Co. has acquired the properties of the Oil State Petroleum Co., the Healdton Oil Co. and the Penn-Oklahoma Oil Co., with total holdings estimated at \$4,000,000 in valuation. The new owner plans for extensive development and operation.

Ontario

HAILEYBURY—Fire, June 27, destroyed a portion of the plant of the Haileybury Brick & Tile Co., with loss estimated at about \$22,000.

Texas

ORANGE—The Reclamation Oil Co., recently incorporated with a capital of \$2,000,000, has plans under way for the erection of a new oil-refining plant on local site. E. J. Pike is president.

CORPUS CHRISTI—The Isthmus Co. is planning for the erection of a new distillation plant in connection with a local gas works, estimated to cost close to \$150,000.

SAN ANTONIO—The Taft Packing Co. is planning for extensions in its local cottonseed oil plant, to increase the daily production to about two carloads of material per day. Plans are under way for the construction of a new fertilizer manufacturing plant at Taft, Tex. Herbert S. Greene, San Antonio, is architect. V. H. Fetick is manager.

FORT WORTH—The White Eagle Refining Co., Augusta, Kan., is planning for extensions and improvements in its local oil refinery.

MARSHALL—The Industrial Gas Co. has awarded a contract to the Hope Engineering & Supply Co., Mt. Vernon, O., for the construction of a new local gasoline plant. With subsidiary works, the new plant is estimated to cost about \$350,000. W. H. Sedberry is engineer.

BROWNWOOD—The Blue Ribbon Refineries, Box 295, is planning for the installation of new filters, driers and other equipment at its oil works. P. J. Baney is president and manager.

Virginia

ROANOKE—The Viscose Co. of America, Marcus Hook, Pa., manufacturer of artificial silk under a chemical process, has plans under way for the erection of an addition to its plant at Roanoke to double the present capacity. The extension, with machinery, will cost close to \$1,000,000. The Ballinger Co., 105 South 12th St., Philadelphia, Pa., is architect.

PORTSMOUTH—The Texas Co., Texas Bldg., Houston, Tex., operating oil refineries, has acquired property, 100 x 600 ft., at Portsmouth, for the erection of a new plant. Preliminary plans are said to be under way.

West Virginia

WHITE SULPHUR SPRINGS—The Cosmopolite Mfg. Co., recently incorporated with a capital of \$25,000, will operate a local plant for the manufacture of spark plugs. G. P. Brown is president and W. M. Sullivan, vice-president.

Wisconsin

MILWAUKEE — The American Metal Products Co., 671 Kinnickinnic Ave., has awarded a contract to the Worden-Allen Co., Washington Rd., for the erection of a new 1-story foundry addition on Bernham Rd. A machine shop will also be constructed.

Capital Increases, etc.

THE PYRAMID BRICK Co., 1007 Scofield Bldg., Cleveland, O., has filed notice of increase in capital from \$300,000 to \$400,000.

THE BLANCHARD OXYGEN Co., Esopus, N. Y., has filed notice of dissolution under state laws.

A petition in bankruptcy has been filed against the **YARDLEY CHEMICAL CORP.**, 50 Union Sq., New York City, by a number of creditors.

THE HANNA FURNACE Co., Leader Bldg., Cleveland, O., producer of pig iron, has arranged for a bond issue of \$4,000,000 for general financing, operations, etc. The company is affiliated with M. A. Hanna & Co., Inc., H. M. Hanna, Jr., is president.

THE WILLIAM E. DEE CLAY MFG. Co., 30 North La Salle St., Chicago, Ill., has filed notice of increase in capital from \$100,000 to \$600,000.

THE DIBBLE COLOR Co., Detroit, Mich., manufacturer of colors, etc., has filed notice of increase in capital from \$50,000 to \$100,000.

THE OCTAGON DROP FORGE Co., 2428 Lowe Avenue, Chicago, Ill., has filed notice of increase in capital from \$30,000 to \$105,000.

THE PORT HURON SALT Co., Port Huron, Mich., has filed notice of decrease in capitalization from \$235,000 to \$10,000.

THE AMERICAN MARINE PAINT Co., 8 Bridge St., New York City, has filed notice of increase in capital from \$100,000 to \$250,000.

THE FIVE POINT CHEMICAL Co., Richmond, Va., recently incorporated, has filed notice of increase in capital from \$25,000 to \$150,000. John B. Brooks is president.

New Companies

THE BIXIE CORP., New York City, has been incorporated with a capital of \$55,000 to manufacture soaps, oils and kindred products. The incorporators are H. N. Henry, R. S. Childs and L. McManus. The company is represented by McKercher & Link, 17 Battery Pl.

THE RUBBER PROINATE CORP., Richmond, Va., has been incorporated with a capital of \$15,000 to manufacture rubber products. A. M. Rubenstein is president, and C. V. Blackburn secretary.

THE MERCHANTS LEATHER GOODS Co., Inc., Providence, R. I., has been incorporated with a capital of \$50,000, to manufacture leather products. The incorporators are Julius Abrams, Charles M. Robinson and Harry Lapen, 65 Moore St.

THE GEORGE F. CROAK FOUNDRY Co., Boston, Mass., has been incorporated with a capital of \$25,000, to manufacture iron, steel and other metal castings. The incorporators are George F. Croak, Athol, Mass., who has been elected president and treasurer; Winthrop Q. Nottage and Gerald M. Croak.

THE SIGNAL PETROLEUM CORP., Long Beach, Cal., has been incorporated with a capital of \$300,000, to manufacture petroleum products. The incorporators are J. C. Rogers, E. S. Dobbin and W. B. Murphy. The company is represented by Desmond & Larzelere, Long Beach.

THE CENTURY MANUFACTURING Co., Buffalo, N. Y., has been incorporated with a capital of \$100,000, to manufacture chemicals and paints. The incorporators are R. A. Maltby, W. N. Carlsile and F. F. Everingham. The company is represented by F. W. Thomas, Ellicott Sq., Buffalo.

THE FRANK MASON CHEMICAL Co., 737 West Madison St., Chicago, Ill., has been incorporated with a capital of \$20,000, to manufacture chemical products. The incorporators are Frank Mason, George E. Krueger and Elmer T. Good.

THE MILLS BROS. Co., Gloversville, N. Y., has been incorporated with a capital of \$200,000, to manufacture leather products. The incorporators are W. E. Mills, D. McEwen and R. E. Toye. The company is represented by F. L. Carroll, Johnstown, N. Y.

THE STATE LINE OIL Co., 28 East Jackson Blvd., Chicago, Ill., has been incorporated with a capital of \$82,500, to manufacture refined oil products. The incorporators are Paul Herbert, E. J. Alexander and B. M. Schlichting.

THE J. F. MOSSER CORP., Boston, Mass., has been incorporated with a capital of \$100,000, to manufacture and deal in tanning extracts and kindred products. J. F. Mosser, 176 Federal St., is president and treasurer; Joseph N. Welch and G. L. Willson are directors.

THE FEDERAL CHEMICAL CORP., Hyattsville, Md., has been incorporated with a capital of \$100,000, to manufacture chemicals and byproducts. The incorporators are William A. Mills, J. L. Humphrey and E. G. Bucklin, Hyattsville.

THE HAMLIN OIL Co., Buffalo, N. Y., has been incorporated with a capital of \$50,000, to manufacture oil products. The incorporators are C. P. Lake and A. Wlberg. The company is represented by W. H. Warhus, Ellicott Sq., Buffalo.

THE COAL GROVE BRICK & TILE Co., Huntington, W. Va., has been incorporated with a capital of \$100,000, to manufacture brick, tile and other burned clay products. The incorporators are T. E. Jeffries, Huntington; and J. W. Lowry, Ironton, O.

THE LANTAGNE LABORATORY, INC., Lowell, Mass., has been incorporated with a capital of \$40,000, to manufacture chemicals, drugs, etc. Joseph T. Lantagne is president; and William A. O'Malley, Draught, Mass., treasurer.

THE MARINE PETROLEUM Co., Chicago, Ill., has been incorporated with a capital of \$1,000,000, to manufacture oil products. The incorporators are L. E. Gowan and A. E. Manheimer, 10 South LaSalle St.

THE CLARK RUBBER SYNDICATE, Rochester, N. Y., has been incorporated with a capital of \$50,000 to manufacture rubber products. The incorporators are F. P. Dunham, I. D. Allen and S. A. Millington. The company is represented by G. V. Holton, attorney, Rochester.

THE S-O-BELL SOAP Co., Kittery, Me., has been incorporated with a capital of \$250,000, to manufacture soap and kindred products. Horace Mitchell is president and D. E. Phillips treasurer, both of Kittery.

THE MONROE OIL & REFINING CORP., Fort Worth, Tex., has been incorporated with a capital of \$1,000,000 to manufacture refined oil products. The incorporators are H. H. Harolson and V. S. Monroe, Fort Worth; and C. W. Perry, Polytechnic, Tex.

THE TENNESSEE METAL TIE Co., Camden, Tenn., has been incorporated with a capital of \$100,000 to manufacture metal ties and other metallic products. The incorporators are Ira L. Presson, J. F. Lindsey and J. M. Holladay, Camden.

THE WOFFORD OIL Co., Birmingham, Ala., has been incorporated with a capital of \$10,000,000 under Delaware laws to manufacture oils and greases. The incorporators are George T. Wofford, J. Gregory Johnston and C. B. Deming, Birmingham.

THE CO-OPERATIVE PAPER BOX Co., Inc., 3502 Cottage Ave., Baltimore, Md., has been incorporated with a capital of \$50,000 to manufacture paper boxes and containers. The incorporators are Benjamin F. Garrett, Edward W. Williams and Alfred W. Watson.

THE GUY LEE LEATHER Co., Philadelphia, Pa., has been incorporated with a capital of \$15,000 to manufacture leather products. Guy Lee, Woodbury, N. J., is treasurer.

THE PHOSPHATE PRODUCTS Co., Mount Pleasant, Tenn., has been incorporated with a capital of \$250,000 to manufacture phosphates, fertilizers, etc. The incorporators are N. B. Stewart and E. E. Fisher, Mount Pleasant.

THE WYOMING DYESTUFF & CHEMICAL Co., Scranton, Pa., has been organized to manufacture sulphur colors, chemicals, etc. A. H. Ney is president and J. F. Higgins secretary-treasurer, both of Scranton.

W. C. DAMBACH, INC., Buffalo, N. Y., has been incorporated with a capital of \$40,000 to manufacture chemicals and chemical byproducts. The incorporators are W. G. Dambach, F. D. Perrin and J. J. Stein. The company is represented by Stein & Barber, Brisbane Bldg., Buffalo.

THE AURORE OIL Co., Syracuse, N. Y., has been incorporated with a capital of \$50,000 to manufacture oil products. The incorporators are A. L. and J. A. McAdam, and J. Bundy. The company is represented by Weils, Neily & Nichols, attorneys, Syracuse.

THE PHE-DER-MOL Co., Inc., Reading, Pa., has been incorporated with a capital of \$100,000 to manufacture special compounds, chemicals, etc. The incorporators are E. E. Clement, A. P. Utt, Reading; and S. B. Wentzel, Pottstown, Pa.

T. VAN AMRINGE & SON, INC., New York City, has been incorporated with a capital of \$60,000 to manufacture petroleum products. The incorporators are I. Kemp, W. R. Halsey and A. Y. Van Amringe. The company is represented by B. C. Meighan, 120 B'way.

THE BREWSTER DRUG Co., New York City, has been incorporated with a capital of \$25,000 to manufacture chemicals, chemical byproducts, drugs, etc. The incorporators are L. Walcott, C. Forbes and J. Rooney. The company is represented by C. A. Winter, 597 Fifth Ave.

THE MONTVILLE PAPER Co., Palmertown Road, Montville, Conn., recently incorporated with a capital of \$50,000 to manufacture paper products, has been organized with E. H. Backes, Wallingford, Conn., as president; C. E. Dunn, Wallingford, secretary, and R. C. Burchard, Montville, treasurer.

THE PERCY OIL Co., Clarksburg, W. Va., has been incorporated with a capital of \$500,000 to manufacture oil products. The incorporators are D. J. Carter and J. W. Woodell.

THE HOME RIDGE OIL Co., 1104 Harris Trust Bldg., Chicago, Ill., has been incorporated with a capital of \$10,000 to manufacture oils, greases, etc. The incorporators are R. O. Farrell, E. F. Brubaker and J. A. Langlands.

THE LUMINO MFG. Co., New York City, has been incorporated with a nominal capital of \$5,000 to manufacture soaps, polishes, etc. The incorporators are A. Podel, W. H. England and M. Katz. The company is represented by E. M. Garbe, 13 Park Row.

THE CORNWALL CHEMICAL CORP., New York City, has been incorporated with a capital of \$50,000 to manufacture chemicals and chemical byproducts. The incorporators are N. Criss, I. Mark and R. Brown. The company is represented by L. B. Bouldin, 110 West 40th St.

Industrial Notes

THE LYONS FAIR will hold its autumn meeting Oct. 1 to 15, 1921, in Lyons, France. This Fair is for the promotion of international trade, and American manufacturers are extended a hearty welcome to exhibit their products. The Fair exhibits all articles manufactured, from clothing to freight locomotives, and include in our field products for general engineering, industrial buildings, india rubber goods, agricultural products, agricultural machinery, etc. Information can be obtained by addressing Emile Garden, 150 Nassau St., New York City.

PAUL H. HSU, a graduate of the Massachusetts Institute of Technology and at one time employed as research chemist with the Larkin Co., Buffalo, N. Y., and also with the chemical division of the Procter & Gamble Co., Cincinnati, O., is on his way to China, where he expects to be engaged in consulting work and marketing of chemical machinery and materials. He requests that manufacturers send him catalogs, blueprints, etc. He can be reached care of Government Institute of Technology, 18 Sic-cawei Road, Shanghai, China.

THE AMERICAN CHEMICAL & SUGAR MACHINERY Co., Philadelphia, announces the Fred W. Kolb, its Pacific Coast representative, has associated with him M. Gillespie and that the business will now be handled by the firm of Kolb & Gillespie, 576 Moradnock Bldg., San Francisco.

ARNOLD, HOFFMAN & Co., 61 B'way, New York City, announce that they are now sole selling agents for the Belle Alkali Co. of Belle, W. Va., manufacturer of pure liquid chlorine, in 100-lb. and 150-lb. cylinders and 2,000-lb. tanks, and electrolytic caustic soda 76 per cent, solid and flake, in large and small drums.

THE WESTINGHOUSE ELECTRIC & MFG. Co. has opened an interplant wireless communication service between the East Pittsburgh plant and the Cleveland foundry. Besides the Cleveland and East Pittsburgh factories, the Springfield, Mass., works and the Newark, N. J., works are being equipped with stations for the transacting of company business.

THE COMBUSTION ENGINEERING CORP., New York City, announces that the sales organization in Philadelphia has been increased and a new service department inaugurated, which has necessitated getting new office space. Its new location is on the tenth floor of the Finance Bldg. The territory is under the management of W. C. Stripe.

THE ASBESTOS STEEL PLATE & SHEATHING Co. has leased warehouse space in the North Pier Terminal Warehouse, Chicago, with suitable offices at 319 North Wells St., to handle business in that territory.

THE ELECTRIC FURNACE CONSTRUCTION Co., Philadelphia, Pa., announces that the Compania Electro Metallurgica Brasileira and the Batcheller-McConnell Co., New York City, have recently acquired from Frank

Hodson, president of the company, and his Swedish associates the exclusive rights and licenses for Brazil for the Gronwall type "Electrometall" electric shaft smelting furnace. Two large furnaces, each of 3,000-kw. capacity, are at present being installed by the Brazilian company.

THE ARMSTRONG CORK CO., Pittsburgh, Pa., announces the following branch office changes: The Armstrong Cork & Insulation Co., Cincinnati, O., moved from 1608 First National Bank Bldg. to 1015 B'way. P. E. Thomas is manager. The Armstrong Cork & Insulation Co., Boston, Mass., moved from 84 North St. to 14 Columbia St. F. W. Robinson is manager, succeeding A. L. Dorr, who recently resigned. The Kansas City, Mo., office address is 529 Lee Bldg., this being only a change in name of the building.

THE FRANKLIN INSTITUTE OF THE STATE OF PENNSYLVANIA, acting through its committee on science and the arts, investigating the jet entraining apparatus of the Surface Combustion Co., New York City, has awarded to the inventor, W. Barton Eddison, the Edward Longstreth Medal of Merit.

H. E. LABOUR, who was formerly connected with the Chemical Equipment Co., has organized a new corporation under the name of the LaBour Co., with headquarters at Michigan City, Ind. This concern will be engaged in the manufacturing and sales business. One of the first units put on the market will be a new type of centrifugal pump invented by Mr. LaBour.

H. G. CARRELL has been appointed sales manager of Wing & Evans, New York City, the sales agents for the Solvay Process Co.

THE METAL & THERMIT CORP., New York City, has recently transferred William Aldrich from the Southern territory to the Western territory. He will travel extensively through California, Oregon, Washington, Idaho, Nevada, Utah and Arizona and will make his headquarters at the new South San Francisco office. William H. Moore, who until recently was assigned to the Chicago territory, now has charge of the Southern territory. This company also announces that in order to handle more satisfactorily its detinning business in the West it has constructed and will shortly place in operation in South San Francisco, Cal., a large new plant for the production of detinned billets, in addition to the detinning plants already operated at Chrome, N. J., and East Chicago, Ind. This new plant has been equipped with a large welding shop containing equipment and facilities for undertaking repairing by the Therman process.

THE TERMINAL ENGINEERING CO., New York City, has added to its staff J. F. McGonigal, formerly of the Foamite Co., and J. H. Potter, a graduate of New York University. M. E. Lyle, for many years with the Columbia Graphophone Co., has been elected a vice-president and is directly responsible for new business, and M. E. Peck has been elected secretary and assistant treasurer.

THE MAGNETIC CO. moved on June 20 into its new plant at 275 23rd Ave., Milwaukee, Wis. The new plant trebles the floor space in the former plant, providing up-to-date facilities for the continued production of its line of magnetic separators.

THE LINK-BELT CO., Chicago, has acquired all of the capital stock of the H. W. Caldwell & Son Co., and Frank C. Caldwell has been elected a director of the Link-Belt Co. The Link-Belt Co. has thus added two new lines, helicoid conveyors and power transmission machinery, to its present line of manufacture. The H. W. Caldwell & Son Co.'s plant will continue to operate under separate corporate existence and under its present name.

THE BROWN INSTRUMENT CO., Philadelphia, Pa., has opened a branch office in Cleveland in the Reliance Bank Bldg., to take care of that district.

PAWLING & HARNISCHFEGGER CO., Milwaukee, Wis., announces that the San Francisco office has been moved from the Monadnock Bldg. to 32 Beale St. At this new address the company maintains a complete service station warehouse and display room for cranes and hoists, machine tools and excavating machinery. R. M. Taylor is district manager.

SAVELL & FROST, of Niagara Falls, N. Y., announce that anhydrous aluminum chloride of high purity is now being produced in commercial quantities at their plant by a process which will make this chemical available for a number of uses requiring a better and cheaper material than has been obtainable heretofore.

THE DOMINION OXYGEN CO., LTD., is breaking ground for a new quarter million oxygen plant at Montreal, which will double the company's present capacity. The build-

ing will be 100 ft. x 100 ft. and will be substantially a duplicate of the company's Toronto plant, which until now has supplied oxygen to Canadian industrial users through five district distributing stations. The Montreal plant will be the second of five producing plants projected at the time the company was organized last year.

Manufacturers' Catalogs

THE DRAPER MFG. CO., Cleveland, O., has issued a very attractive catalog, No. 7, entitled "Steel Barrels for All Purposes." The first section illustrates and describes the various types of steel barrels and gives their capacity, dimensions, cubic space, weight and average number to car load. The Interstate Commerce Commission tests to which these barrels were subjected are explained. Pages 103 to 160 contain useful tables not ordinarily found in a catalog of this type. This feature makes the booklet of unique value.

THE PAWLING & HARNISCHFEGGER CO., Milwaukee, Wis., has issued two new leaflets, on shovel attachment for P. & H. types 205 and 206 excavator-cranes.

THE STEERE ENGINEERING CO., Detroit, Mich., has issued a pamphlet on "The Intensive Scrubber for Recovery of Ammonia from Coal Gas."

THE GRISCOM-RUSSELL CO., New York City, has issued Bulletin 1140, on Stratton team Separator, and a pamphlet on G-R expansion joint.

THE CHICAGO PNEUMATIC TOOL CO., New York City, has issued Bulletin 648, which describes little giant geared air hoists, motors and winches. This bulletin shows application views of this hoist in various industries and for innumerable operations, such as handling steel plates in storage yards, serving sheet steel to cutting machine at large boiler shops, etc. Copies will be sent to those interested, upon request.

THE CAROLINA, CLINCHFIELD & OHIO RY., Johnson City, Tenn., has issued a booklet on "The Mineral Resources of the Clinchfield Territory."

CARRIER AIR CONDITIONS CO. OF AMERICA, Buffalo, N. Y., has issued Catalog 480, on "Carrier Air Washers and Humidifiers," which is well illustrated.

THE PACIFIC TANK & PIPE CO., San Francisco, Cal., have issued Catalog 14 on "Pacific Wood Stave Pipe." This attractive 128-page catalog is the first pipe catalog this company has issued for a number of years and is the result of study of wood pipe for the past thirty years. Illustrations and description of some installations are given of Pacific wood-stave pipe and the various kinds of joints, fittings, valves, etc., that are used of both types—viz., "Continuous-stave" and "machine-banded." Tables have been inserted based on formulas resulting from an extensive series of investigations made by the U. S. Government. These are conceded to be the latest word on the subject of flow water through this kind of pipe. In the final section is a description of several Pacific products closely allied to the manufacture of wood-stave pipe.

THE PETROLEUM RECTIFYING CO. OF CALIFORNIA has issued a catalog on the Electrical Process for the Dehydration of Crude Oil Emulsions.

THE SULLIVAN MACHINERY CO., Chicago, Ill., has just issued Bulletin 78-A, which describes and illustrates dry vacuum pumps, single cylinder, steam and belt driven. These pumps are equipped with improved wafer type plate valves for both intake and discharge openings. The Sullivan Turbine Hoist is another new product, which is described in Bulletin 76. These hoists are used in mining of coal and metal and in many phases of industrial work.

THE WHEELER CONDENSER & ENGINEERING CO., Carteret, N. J., announces the publication of the 1921 edition of its "Steam Tables for Condenser Work." This is the sixth edition. The tables are in book form, pocket size. The properties of saturated steam are tabulated from 29.8 in. vacuum to atmospheric pressure in increments of tenths of an inch referred to a 30-in. barometer. The values were especially calculated for this book by Prof. Marks. As it is customary in vacuum work to read vacuum in inches of mercury, this is superior to the old method of giving absolute pressures in lb. per sq. in. Above atmospheric pressure the increments are in pounds gage. The book explains how measurements are made by means of the mercury column and barometer, and gives

constants and tables for making corrections. Corrections for the thermal expansion of mercury, for the relative expansion of mercury and brass scale, and other corrections are included.

THE PFAUDLER CO., Rochester, N. Y., has issued a new booklet on "Glass-Lined Steel Equipment," such as mixing tanks, stills, pots, crystallizing pans, etc. The company's research laboratory is featured as being the power behind the sales organization.

New Publications

BOOKS

SWEET'S ENGINEERING CATALOG, Seventh Annual Edition. Compiled, edited and published by Sweet's Catalog Service, Inc., New York. Cloth, 1251 pages; illustrated and indexed.

Sweet's Engineering is a catalog filing system which contains the separate catalogs of about seven hundred manufacturers. The field it covers is that of engineering and power plant equipment, or, to quote more definitely from the preface, it lists "Materials, equipment and supplies relating to the practical construction, equipment and maintenance of all projects of an industrial or engineering nature." In other words, the products it describes range from drawing boards to dynamos and from lighting receptacles to locomotive cranes.

The seventh edition of Sweet's Engineering, which has just appeared, marks an improvement in many ways over those which preceded it. The products index, for example, has been revised and simplified, so that it is now much easier to locate any desired information. This information, in turn, has been arranged in a more logical fashion. Even the appearance of the book has been improved by a better balance of cut and by the use of a better quality of paper. The new edition is smaller, lighter and easier to handle, although the number of pages in the volume and the number of firms represented show a marked increase.

TEXT BOOKS ON THE MANUFACTURE OF PULP AND PAPER. Five volumes. Price, \$5 per volume. Published by the Joint Committee on Vocational Education of the Pulp and Paper Industry, Thomas J. Keenan, secretary of T.A.P.P.I., 542 Fifth Ave., New York City.

Volumes I and II of this set deal with arithmetical calculations, elementary mathematics, drawings, etc. Volumes III, IV and V, to be issued shortly, will deal with pulp woods and their preparation, manufacture of pulp, analytical methods and all aspects of paper manufacture. In the selection of classroom problems bearing on the principles and practice of pulp and paper manufacture these books represent a high standard in text book publishing.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY's summer meeting will be held at Canton, Alliance, Sebring and East Liverpool, Ohio, July 25 to 27. Headquarters will be at the Hotel Courtland, Canton, Ohio.

AMERICAN CHEMICAL SOCIETY, THE SOCIETY OF CHEMICAL INDUSTRY and the American Section of the latter society will hold a joint meeting in New York, Sept. 6 to 10.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in Lake Placid, N. Y., Sept. 29 and 30, and Oct. 1.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its fall meeting at Wilkes-Barre, Pa., Sept. 12 to 17.

AMERICAN MINING CONGRESS AND NATIONAL EXPOSITION OF MINES AND MINING EQUIPMENT will hold its twenty-fourth annual convention in the Coliseum, Chicago, Oct. 17 to 22.

AMERICAN SOCIETY FOR STEEL TREATING will hold its third annual convention and exhibition Sept. 19 to 24 at Indianapolis.

THE NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SEVENTH) will be held during the week of Sept. 12 in the Eighth Coast Artillery Armory, New York City.

NEW JERSEY CHEMICAL SOCIETY has discontinued meetings for the summer and will resume them in October.

SOCIETY OF CHEMICAL INDUSTRY (BRITISH) at the invitation of the Montreal section will hold its annual meeting in Montreal and other Canadian cities during the week of Aug. 29, 1921. Details will be printed in this magazine from time to time.

Culture in Technical Education

AT THE twenty-ninth annual meeting of the Society for the Promotion of Engineering Education held at Yale University a few weeks ago, Prof. WILLIAM H. BURR, formerly professor of civil engineering in Columbia University, criticized the society for what he regarded as neglect to bring engineering education to such a plane that engineering as a profession would be elevated to a parity with law and medicine. The burden of his criticism was that the present four-year course in engineering, as given at most institutions, is quite inadequate to enable the graduate to command professional respect or discharge his highest duties as an engineer and a citizen. Characterizing the four-year course as a "college scientific course" and admitting that it had served a good purpose, he contended nevertheless that the time has arrived when a greater proportion of liberal arts must be mixed with science and engineering in order to reach a higher goal for engineers. He advocated a six-year course following high school preparation, devoting three years to liberal arts and three to engineering.

The subject has been before engineers and engineering teachers long enough so that more should have been accomplished than is evident. We are reminded of MARK TWAIN'S comment on the weather, when he said that everybody was always talking about it but nobody ever did anything about it. The situation in engineering education is not exactly parallel, because something has been done. The six-year course is established at Columbia University and other institutions have their combination undergraduate and graduate plans. For the most part, however, the four-year course prevails.

Prof. BURR has our support and approval. When the subject was still in the abstract we were convinced on general principles, supported by observation, that engineering and technical graduates were losing necessary breadth and culture through too close confinement to technical studies. It was apparent even then that a change would not be effected save by heroic action on the part of college faculties, because the necessity for study of the liberal arts could not be appreciated by young students. They were restive under instruction in subjects which had no apparent "practical" bearing. They itched to get into the field. But broad vision and sound counsel have prevailed in some quarters and the student is being better educated in spite of his personal predilection.

Considering the engineer as a citizen, we think that he can rise to even higher places of authority and responsibility than are now held by the lawyer and physician and that the community can learn to look up to him with greater confidence and assurance than they now show toward our public servants. But this will not be possible unless the engineer is given a broader

foundation than can possibly be built on technical studies. The lack may not be apparent in the first few years out of college, when competition for professional recognition and preferment is keen, but at forty the liberally educated engineer will surpass and excel his narrowly trained colleague, not only in general affairs of life but perhaps in engineering as well. The problem before the Society for the Promotion of Engineering Education, as we see it, is to discover those fundamentals in engineering education that will produce men who in their mature years will command not only professional respect from their colleagues but also recognition and approval from society in general. The details of the course of instruction can then be left to individual educators.

Ford Proposes to Buy Government Nitrate Plant

UNUSUAL interest attaches to the offer of HENRY FORD to purchase Nitrate Plant No. 2 at Muscle Shoals and to lease the Wilson dam. The disposition of these war-time projects has been a matter of great concern to the War Department on account of the vast sums already invested and the additional millions required to complete the dam and power plant. Our readers will recall that one solution proposed by Secretary Baker was the creation of the United States Fixed-Nitrogen Corporation to acquire and operate the nitrate plant, the dam and power plant to be completed at Government expense. Congress refused to create the proposed corporation, and declined to appropriate further money for the completion of the dam, work on which was stopped last Spring. With the change of administration Secretary Weeks finally announced that the nitrate plants would be retained under Army control in the most economical standby condition, but that he would not recommend an appropriation, estimated at about thirty million dollars, for the completion of the dam unless he could find private business interests that would assure him of the commercial utility of the project and agree to take it over and operate it when completed. Under such conditions he expressed himself as willing to recommend the necessary appropriation by Congress.

It is too early to determine whether Mr. Ford's proposal in detail will be satisfactory to the Secretary, though on its face it appears to conform to the announced requirements and will call for sincere consideration.

A number of interesting speculations may be indulged in. Has Mr. Ford definitely allied himself with the agricultural interests that have been urging Government operation of the nitrate plants for the production of fertilizer? Will his definite offer lend encouragement to the Congressional bloc that has

shown non-partisan strength in agricultural matters? How will Congress look upon Mr. Ford's offer in the light of its previous defeat of proposed legislation looking to the formation of a corporation to operate the nitrate plant and appropriation for continuance of work on the dam? It looks as though Congress and Secretary Weeks would be embarrassed if they now refuse to entertain this bona fide offer from a private source.

Seen Through

Friendly Eyes

IT IS not so many years since it was a fixed habit of a few critical travelers from Europe to come to this country for a few days, and after seeing New York City and Niagara Falls return home to write their impressions. Probably there was an equal number of Americans who were guilty of the same performance in regard to Europe. Having made a few isolated observations, they promptly drew general conclusions which illustrated mainly their lack of intelligence. Conditions are much improved today, however, because people on both sides of the Atlantic have taken pains to see more of the countries they visit. Intelligent Europeans no longer think they are in the West when they reach Pittsburgh—in this respect surpassing some of our natives. Nor do Americans think that they have seen England or France through a business trip to London or Paris.

It is always refreshing to read the impressions of an intelligent and alert visitor who is familiar enough with conditions at home to enable him to make his comparisons and draw his conclusions rationally. If it so happens that he is of our trade or profession, the more interested are we in his observations on things in general, because we may assume that he sees them through eyes trained much like our own. Accordingly we looked forward with pleasure—and were not disappointed—to the impressions of ERNEST J. P. BENN, of the *Chemical Age*, London, who made a recent business tour of the United States. In a delightful address before the New York Business Publishers Association Mr. BENN gave an intimate view of industrial conditions in England, and after he returned home he published in the *Chemical Age* a very frank and illuminating statement of his impressions regarding ourselves. The fairness of his judgment in the latter case only serves to lend confidence in his appraisal of conditions at home.

Observe the frankness with which he endeavors to convey his opinion that the trouble with England is that it is "absolutely steeped up to the neck in socialism," of innumerable brands, all having their roots in the broad conception that there is something wrong with private enterprise, private property, wealth and profit, and claiming that we must produce for use and not for profit. As a remedy for this distressful condition he sees the need of a crusade in England on behalf of a true understanding of that system of thrift, work and economy called capitalism, which offers opportunity for individual initiative. Contrasted with this condition in England, the American socialist, in Mr. BENN's eyes, is of a pale, anæmic variety, quite incapable of qualifying for membership in the English Socialist party.

But if Mr. BENN failed to find socialism rampant in this country it did not affect his observation of that outstanding difference between industry in England and America—quantity production by mechanical means.

He sees us devoted also to personal efficiency, which is largely responsible for the fact that we accomplish more per unit of time than do our English friends. He reaches the conclusion that even prohibition is accepted in principle as "a weapon in international industrial competition." In his mind it is "the greatest force to be reckoned with in the world today." Efficiency in industry and in personal matters is seen by Mr. BENN as a fetish of the American people.

There is encouragement for American industry in these views on the part of one who has studied industrial conditions in England and observed them critically in the United States. When we are inclined to think that we have trouble with labor and production, we can find solace in Mr. BENN's conclusion that "America is not heaven, but it is, as I see it, as near to an economic heaven as we mortals shall ever approach."

Readjustment

Or Economy?

A FEW months ago all the talk about business affairs generally was that we had entered a period of readjustment. The thought was that the period would be a short one, in which we should simply revise our price lists and things and then business would go ahead much as formerly. The most common remark was that buyers had gone on strike, the idea of a strike of course being that the striker has certain terms and will go to work whenever he gets those terms. The common thought seemed to be that the buyers would win the strike and that would be the end of it. It was all very simple. If a manufacturer could not sell profitably at the prices bid, all he had to do was to reduce his costs. If workmen wanted wages that were too high all that was necessary was for them to be idle a few weeks, or possibly months in the case of the most recalcitrant, and then they would be back at their old jobs, simply working for less money. The bright remark was made that this industrial depression was different from those of the past in that the people knew this time precisely what they were waiting for.

We all know better now. It is much more than a readjustment. It is vastly more than a revision of price lists and wage scales, much more even than a change in men's minds whereby they will kindly become willing to work harder for society, whether in making profits or earning salaries or wages. We have to build up afresh. We must not only become willing to work, we must find a job, or devise means whereby we can render better service.

It is only a few months ago that the main thought was about prices. They would have to come down, and the idea was that as soon as they had come down they would start advancing again. That is not the natural course of affairs. During the war and for a time afterward an "endless chain" was much spoken of, whereby one advance brought on another, and so around a circle. There was an ascending spiral. Can there not be a descending spiral? Dr. RALPH G. HURLIN, statistician of the Russell Sage Foundation, has answered this question, by carrying an index number of commodity prices in the United States back to 1810. This shows that after the war of 1812 there were generally descending prices for about thirty years, then advances culminating in the Civil War, after which there were declining prices for about thirty years, advances then culminating, as we all know, in

1920. One may say that things are different now, but a sapient observer in 1865 might have pooh-poohed the statistics of what followed the war of 1812—that was ancient history! Of course a war does not cause advancing prices for thirty years before it occurs. Quite likely the general or normal trend is upward, but a war sends prices so much above normal that it takes many years for complete return to normal. Dr. HURLIN'S figures, by the way, shows the three war peaks to be of practically the same height, and there is no great difference in the two troughs.

It is not a quick readjustment, something to be got through with, but simply years and years ahead of us of hard work, economy and striving for greater and greater efficiency. It is not a case of waiting until the thing is done. The matter of prices is a statistical detail. From about 1896 to 1920 the trend in prices and wages was generally upward. Those who succeeded by reason of that fact will have to adopt a new philosophy. Those who succeeded because they were economical and efficient will not have to change. There will be no success in waiting for prices to come down or in waiting for them to go up. Success will come in reducing costs, and then reducing them more.

Concerning the Threefold State

OUR READERS may recall that in our issue of May 25 we gave the index number of various commodities showing average prices for April of this year as compared with those of 1913 at 100. We recorded farm products as 115, foods 141, clothing 186, building materials 203, housefurnishing goods 274, etc., and it seemed rather hard for the farmer getting 115 for his product to pay 274 to furnish his house.

The fact is and always has been—as a general rule, of course, and subject to modification—that everyone gets as much as he can for his work or his wares. The trouble is that some trades are able to jockey for position while others are not. In our present situation there are occupations which do not call for intelligence above that of a child of twelve or fourteen years, requiring hardly any preparation and involving no personal responsibility, which are better paid than work calling for long years of professional training. Coincident with this we have a great deal of unemployment and not a little suffering from actual want.

Collective bargaining has great merit, and we doubt if employers of labor as a whole are good enough to get along without it. But collective bargaining, as we call it, is a misnomer. It is rather group bargaining, and the separate groups often play havoc with the general welfare. It has also a degrading tendency on skilled labor, for it destroys initiative and sometimes discourages specially good work. By including unskilled labor in certain occupations it has made a hod-carrier a \$10 man, while the draughtsman in the architect's office who is a graduate architect gets \$30 or \$40 a week. We do not begrudge the hod-carrier his \$10 a day, or whatever he gets; we object only to the high price that his less lucky brother must pay for rent in consequence of increased building costs. What we lack is co-ordination in the rewards of labor that would provide for the welfare of all.

All sorts of remedies have been proposed for the former evil which obtained when employers fixed wages and the present one when leaders of separate groups of laborers fix them for those they represent, but the

right way does not seem to have come into function. Now comes a new proposal by Dr. RUDOLPH STEINER, a Hungarian, whose book "The Threefold State" has had a great sale in Continental Europe and in England, but as yet has not got into general circulation here. Dr. STEINER holds that most of society's ills are due to excessive centralization. He describes the contradictory forces at work and proposes to separate the fields of human endeavor into a trinity of departments, viz.: into the Economic, the Political, and the Spiritual State.

The Economic State is concerned with materials, with the most economical production, and the distribution of commodities. It is business; it employs labor, but does not fix wages. Labor is not a commodity, and to confuse the function of men with that of materials leads to trouble every time. We have not his book, but are informed that business may be conducted under such an economic state in a manner similar to that which now obtains except that employers shall have no voice in fixing rates of wages or hours of work. If the cost of labor is too high business will not undertake the venture.

The Political State fixes and adjusts the rates of wages for all crafts and all labor, and the hours of work. This is done by the people's representatives as a whole, and therefore all dispute between employers and employees as to wages and working hours shall come to an end. Then politics will not fix the pay for a few favored ones very high and let the others starve. If carrying a hod is worth \$10 a day and plasterers should get \$15 to \$20 for what they call "bankers' hours" (which are the hours of banks' customers rather than the hours of the bankers themselves), then these rates will rule. If, however, such wages make rents too high, the chances are that politics will bring them down, for there are too many printers, clerks, street railway employees, policemen and miscellaneous people for hod-carriers and plasterers to rule politics. Whatever politics says in regard to labor, goes.

The so-called Spiritual State includes education, the guarding of individual liberty, and is to hold the individual genius free from outside control.

That is the rough outline from a brief review of the proposal that is being widely read and considered in Europe. An industrial company called the Futurum Co., Ltd., with \$1,000,000 capital has been organized to carry on manufacture under Dr. STEINER'S plan at Dornach, near Basel, in Switzerland. The proposal has to do with governments rather than with corporations, as we understand it, but the projectors of the Futurum Co. are so certain of the merits of the plan that they believe their methods will become general and accepted by all.

We hope the book will soon become available, for it behooves us to keep posted on the ideas that are spreading. Had more intelligent persons who are familiar with the actual problems of administration made themselves thoroughly familiar with the socialist theories we might have been delivered from much of our present trouble. Many readers have been misled because they lacked the vision that comes from experience, and there has been lacking the quality of criticism that speaks from experience. We are free to confess that the Threefold State looks rather raw at first glance, but for all that it certainly deserves careful and sympathetic study. The present chaotic method of fixing wages by means of strikes and bludgeons is not sound.

Readers' Views and Comments

Heterogeneity in *Canis Variegatus*

To the Editor of *Chemical & Metallurgical Engineering*

SIR:—Having noted in a recent issue of your English contemporary the *Ironmonger* brief mention of an important research by my friend, Dr. B. Feeter, F.R.S., M.I.V., F.O.O.L., etc., etc., I take the liberty of forwarding you this somewhat more extended account of his remarkable findings, hoping for its hospitable reception in your columns. Dr. Feeter, as is well known, was the Kitchener Research Scholar for 1901, and Fitts medalist in 1903. His latest investigation into scientific technology is "On the Variations in the Distribution of Currants in Spotted Dog."

Spotted Dog, as it is perhaps unnecessary to point out, is the English urchin's pet name for a goody which to know is to appreciate. However, the question of the rendering in correct scientific language of the term "Spotted Dog" has been a matter of anxious consideration to the editor of the *Ironmonger*. It was finally concluded that the choice lay between *Canis variegatus* and *Canis maculatus*. The objection to *variegatus* was that, though the adjective might pass if the object under examination had been a pink or a peony, a variegated dog, and still more a variegated pudding, were monstrosities, even in Latin. On the other hand, *Canis maculatus* suggested not only a spotted dog, but a blotched or pimply dog, and even, if taken in its ethical sense, an immoral dog. What clinched the matter was the discovery that in the text about the leopard and his spots, spots is given as *varietates*. But anyway, says the editor rudely, one spotted dog-Latin word is as good as another. So his article was entitled "An Investigation of *Canis Variegatus*."

Dr. B. Feeter points out, in the first place, that it has long been recognized that marked irregularities occur in the distribution of currants in spotted dog. For example, Van p'Uff showed in 1907 in the *Archiv für Küchenwissenschaft*, Band CXIX, Heft 497, that in fifty commercial specimens examined by him there was marked segregation toward the center, and when this was excessive was very detrimental to its cohesion and general rigidity. Dr. P. L. Um proved, in *Wirtschaftliche Mitteilungen von Podingswesen*, for Jan. 15, 1908, by taking consecutive sections that currants were entirely absent from the extreme ends. Mr. P. R. Ice, in comment on this work, showed that little objection would be encountered from the purchaser if the currants were deep seated, that is subcutaneous, and not contributing to any surface defect. Mr. Chowder, in the National Quizzical Society's Memoirs for 1909, reviewed all the work of experimenters and propounded the theory that is now associated with his name. Mr. Chowder's hypothesis, as is well known, is based almost wholly on the assumption that the distribution of currants is effected solely by heat-treatment, and he rejects the hitherto accepted theory that it is caused by a lack of homogeneity in the plastic mass.

In order to test the soundness of this theory the author, with the advice and assistance of Prof. Costard, entered upon the research which is here recorded.

It had been suggested that a simple method of procedure would be to watch a number of spotted dogs

during the processes of manufacture, but this plan was rejected as both unscientific and unlikely to require the thousands of observations that are demanded by a modern research. It was felt that the correct course to pursue was as follows:

1. To obtain as large a number of spotted dogs as possible, and here it is proper to record special indebtedness to the co-operating concerns, who in the interest of science, and for the upbuilding of their product to technical excellence, have so generously supplied the specimens.

2. To make a complete analysis of each specimen.

3. To take consecutive sections (a) in a horizontal plane, (b) in a vertical plane, (c) in a plane inclined to the vertical, (d) in a plane inclined to the horizontal, (e) in tangential planes at intervals of five degrees round the circumference, and (f) in a left-handed spiral extended from the apex at one end to the apex at the other.

4. To test the specimens thus secured by tensile, bending, impact and torsion, both in the state as received, after having been fully annealed, and after a quenching. It was recognized by Dr. Feeter that these were not strictly required for the research, which, it may be remembered, was merely to study the *distribution* of currants in *Canis variegatus*. However, we are more clearly coming to perceive that the normal failures are not giving us the trouble to explain as are the abnormal, and the latter are doubtless due in the last instance to submicroscopic segregation. Consequently, any investigation into segregation has a special application in this direction. Furthermore, it was thought that the results of such a series of tests as in item 4 would furnish a volume of data which would enable a comparison with the results being obtained by the International Joint Co-operative Investigation of the Effect of Sulphophosphates on Meal.

5. To determine the hardness by the Brinell method and by the scleroscope.

6. To examine all specimens by reflected, transmitted, plane polarized light, and to determine, if possible, the number of currants per meter cube by counting the fragments of seeds as seen in an oil immersion microscope.

To carry out this program in its entirety no less than 12,500,764 separate observations had to be made, but the results have fully justified the work involved.

The original manuscript starts out by giving a description of the apparatus employed (which occupies seventy-five pages of his paper and is accompanied by forty-nine drawings and photographs). Then follows a tabulation of the results in 963 tables. It is much easier to appreciate the findings by examining the graphs which are attached to the original manuscript, 742 in all.*

CONCLUSIONS

1. It has been finally proved that dimorphic allotropic forms of dough (α dough and β dough) may exist side by side in a single specimen of the size used in these tests. The exact nature of β dough is unknown; Prof.

*Unfortunately it will be impossible to reproduce even a few of these remarkable diagrams on account of a lack of space.—[Ed.]

Costard holds that it is a true allotrope, although pseudomorph after another modification. B. Feeter, however, contends that it is a transitional form, between alpha and a hypothetical gamma state, which latter are thought to be the stable varieties. Beta is therefore probably a solid solution, or perhaps an allocolloid. Further research is necessary to clear this important point.

2. That undoubted segregation of currants does occur, being greatest toward the center of length and the middle third of the height.[†]

3. That segregation is irrespective of the nature of the dough, but

4. Is due in some manner that it was impossible wholly to determine to the heat treatment.

5. The determination of the $Ar_{1,2,3}$ points by means of the Le Chantecler pyrometer is rendered extremely difficult by reason of the freezing of the eutectic before the currants have gone into solid solution.

6. Several marked examples of twinning were observed, and the appearance of slip-bands supports Dr. Rosenfield's theory of viscous flow in the intercrystalline amorphous cement.

It should be noted that owing to a misunderstanding on the part of the laboratory boy, who is now suffering from fatty degeneration, the specimens set apart for observations on season-cracking were destroyed. Many instances of fire-cracking have been reported by the manufacturers, and it has been suggested that the Kitchener research fund make a further grant to determine this very practical commercial aspect of the question.

MARTIN SEYT.

Industrial Alcohol and Prohibition

To the Editor of Chemical & Metallurgical Engineering

SIR:—The article on "Industrial Alcohol and Prohibition" in the June 22 number of your journal is most illuminating. Dr. Whitaker struck the keynote when he said that the public, to say nothing of the prohibition enforcement agents, need education on the subject of the industrial importance of alcohol.

Words and letters are great teachers, but the greatest of all is experience. Suppose the alcohol producers of the United States refuse to produce or sell alcohol for any purposes whatsoever until the ridiculous enforcement and interpretation of the laws is done away with, and the legitimate use of pure and denatured alcohol is aided and encouraged as expressly provided for by the Volstead act.

Let the overzealous narrow-minded prohibition enthusiast go to the drug store and find that his favorite antiseptic, hair tonic, mouth wash or the simple household remedies such as tincture of iodine or spirits of camphor are either selling at a fancy price or not available at all—and his wife go shopping only to find that perfumes, flavoring extracts, celluloid articles, certain shades of cloth are not in stock. Let them both understand when they ask the reason for this state of affairs that alcohol is necessary for the manufacture of these articles, but that its sale and manufacture have been made so intolerable they have been temporarily abandoned.

Let the public learn by experience, if we cannot convince them any other way, the importance of industrial and medical alcohol. I dare say it would be only

a few weeks before the prohibitionists themselves would rush to make amends or pass legislation requiring the manufacture and sale of alcohol for legitimate purposes, which would accomplish the desired results.

In other words, let the public learn by experience, the quickest and best teacher, and the narrow-minded prohibitionist have his heart's delight—remove alcohol temporarily from the market.

Even if research, college and control laboratories have to close for a few months, the sacrifice will be worth the victory. Science must save her master tool, alcohol. For chemistry to go without alcohol is like trying to run an automobile on three wheels.

Malden, Mass.

EDWARD O. HOLMES, JR.

Recovery of Volatile Solvents by Bregeat Process

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have read with interest the article by Messrs. Roulleux and Dort on "Recovery of Volatile Solvents by the Bregeat Process," and must compliment these gentlemen on the interesting data given therein, which will, I am sure, prove of considerable interest and service to many users of solvent recovery systems.

The industrial application of the Bregeat process is, of course, more or less similar to the application of other systems of solvent recovery in its principal points, and I do not wish in any way to decry the methods put forward or the results obtained.

There are only one or two statements in the entire article which I feel, in justice to several other processes available, should be corrected. While I am not personally familiar with the development of the Bregeat process in France prior to 1917, I am quite certain that processes for solvent recovery based on accurate scientific principles were in operation in Great Britain and this country before that time. I am personally familiar with the construction and installation of one plant in Great Britain for the recovery of ether-alcohol mixture from cordite manufacture, with which the Bregeat company had nothing to do whatever. I am also familiar with another installation in Great Britain, in 1915, which made use of a crude cresylic oil for the absorption of ether, alcohol and acetone mixture and, of course, in Great Britain crude creosote oil has been in use for many years for the absorption of benzene from coke-oven gases.

I wish to correct one or two statements in the summary, in which it is stated: "Until the Bregeat process had been developed the solvent recovery was not an industry itself. The Bregeat process is responsible for bringing solvent recovery out of the class of an incidental and casual art into that of an independent and well-established business."

It seems to me that these two statements require considerable modification in justice to both British and American firms which have been building and installing solvent recovery equipment of the highest type for several years. In Great Britain, I mention my own firm of Blair, Campbell & McLean, Ltd., of Glasgow, Scotland, which was probably the first in the field, and in this country Messrs. Badger of Boston, Lummus of Boston and finally, the American offshoot of Blair, Campbell & McLean, Ltd.—namely, the American Chemical & Sugar Machinery Co., which in co-operation with the Lewis Recovery Corporation of Boston has developed the explosion-proof solvent recovery system.

Solvent Extraction in the Vegetable Oil Industry

Principle Involved in the Solvent Extraction of Oil From Vegetable Oleaginous Materials—Commercial Development of the Industry—Stationary and Rotary Types of Extractors—Principal Solvents—Economic Considerations—Uses of Products Obtained*

BY J. H. SHRADER, PH. D.
Formerly Chemical Technologist, Bureau of Chemistry

FOR a great many centuries man has obtained vegetable oil from fruit and seed by applying pressure. One of the earliest applications was that simulating the simple mortar and pestle, whereby the operator broke the oil cells by pounding a small lot of the oil-bearing material in a heavy container and collected what oil flowed freely. An early application of power was the grinding mill operated by a bullock. Then were developed powerful edge-runner grinders in which the oleaginous material placed in a rotating pan was ground by vertical grindstones running on their rims. The direct application of static pressure to given lots of oleaginous material was the old wedge press, wherein the charge was bagged or wrapped in some sort of heavy cloth, placed in a frame and subjected to a pressure of many atmospheres by driving heavy wedges between the cake and a head block. Following this, the hydraulic press was developed, whereby the wrapped cakes of oleaginous material were subjected to powerful hydraulic pressure. A more recent development is the hydraulic cage press, whereby two or three times more pressure is applied and a steel basket is substituted for the cloth wrapping of the cake. In the best of these the cake still carries about 4.5 per cent of oil, and more usually about 5.5 to 6 per cent. Many mills cannot produce even as well as this.

In view of the ready solubility of vegetable oil in several volatile solvents and the universal laboratory application of this to the exacting requirements of quantitative analytical procedure, it is to be expected that effort would be made to apply it to industrial operations. This was successfully done about seventy-five years ago.

The principle involved embraces grinding the oleaginous material to such a degree that the oil cells are broken as much as practicable, and then treating the mass with an excess of some volatile solvent such as gasoline or benzene, drawing off the oil solution from the extracted residue (or pomace, as it is called), and distilling the solvent from the oil. The solvent is returned to storage and used for subsequent extraction. The process sounds simple, and so it is theoretically, but as an industrial operation it is somewhat involved and requires a high degree of technical attention to be a successful commercial enterprise.

COMMERCIAL DEVELOPMENT

The advantages and simplicity of the solvent extraction of oils early led to its application to the olive-crushing industry. The residues left after expressing as much oil as possible are treated usually with carbon bisulphide; hence the trade name, sulphur oil. This oil is of low grade, caused not only by the solvent used—

namely, carbon bisulphide—but also due to the residues having been previously pressed, macerated with water, heated and again pressed, often several times previously to extraction with solvent. Such technical mistreatment probably accounts in a large measure for much unfavorable criticism of extracted oil.

Before the war a large industry grew up in Germany based on the extraction of oil-seed cake which contained a particularly high percentage of oil. The inefficient crushing performance of tropical native and even more or less modern mills was the basis for this thriving industry and high-oil cake was shipped all the way from the Philippines to Hamburg. German firms were growing rich on what others wasted. Usually gasoline or one of the chlorinated hydrocarbons was the solvent. Both the oil and the meal were successfully marketed, although at a discount because of the quality produced.

For years the solvent extraction of oils has been practiced in England on a large scale. This has been quite successful, as is manifest from the favorable criticism appearing in the literature.¹ Extracted oil of high grade is now made for edible purposes, particularly for use in the margarine industry, but opinion differs as to the uniformly satisfactory character of the finished oil. This extracted oil is refined and deodorized following practices similar to those applied to hydraulically produced oil. A recently equipped mill has a capacity of 1,200 tons of raw material per week. Some mills produce their entire tonnage of oil by solvent extraction, without applying a preliminary hydraulic pressing to the oil-bearing material.

It is common knowledge that in Manchuria a soybean solvent extraction plant was installed several years ago and is apparently being operated satisfactorily. Several more such plants are now being introduced into Japan.

In the United States the use of solvent extraction has not been an unqualified success. Four concerns applied it to extracting linseed oil from flaxseed, using gasoline and the stationary percolator type of extraction machinery. One plant after another was discontinued until at the present time none of these plants is extracting by solvent. Much trouble was experienced in marketing the meal due to the difficulty of removing therefrom the residual traces of solvent. This unsatisfactory performance has become so widely known that today it is presented as irrefutable evidence of the futility of the method, notwithstanding the fact that modern practice has greatly improved the procedure by using improved equipment and better solvent. Only in the manufacture of castor oil and recovery of low-

*Prepared in connection with work done in the Office of Drug, Poisonous and Oil Plant Investigations, Bureau of Plant Industry.

¹*Oil and Color Trades Jour.*, Dec. 13, 1919, p. 2281; *Margarine and Allied Trades Jour.*, vol. 1, p. 382 (January, 1920).

grade industrial greases and fats does solvent extraction play a necessary and generally recognized part.

At the present time several extraction plants in this country are operating apparently satisfactorily on various vegetable oil-bearing materials. They are extracting coconut oil cake and parings, cottonseed, cottonseed cake, corn germs cake, castor beans, palm kernels, pine-tree wastes and other miscellaneous oleaginous materials. One plant here is said to be making a solvent extracted oil of edible grade for cooking purposes after refining and deodorizing it. Then, in addition to these,

This finds its greatest application in treating garbage and slaughter-house wastes. Several such plants are in active operation in the United States.⁷ Since, however, this is a special line, it is not discussed here.

TYPES OF EQUIPMENT

The machinery used in the solvent extraction of vegetable oil and other fat-bearing material consists of two general classes—namely, stationary and rotary. In the former the extraction unit is essentially a stationary tank, usually with its longer axis vertical, and

FIG. 1. SECTION OF EXTRACTION PLANT OF GERMAN TYPE

several plants are engaged in extracting the residual fat from bones and other animal wastes.

Thus this industry is fairly well developed. It has a foothold in the leading countries engaged in producing oil and is not only holding its own but is growing. Although originally developed for treating materials producing inedible oils and fertilizer, it has been so improved that now it is being increasingly applied to the production of oil and meal of edible grades. Among the materials treated by this process have been:

Palm kernels	Olive residues
Coconuts (fresh)	Rice bran
Copra	Fish residues
Rapeseed	Fullers earth
Soya beans	Pine chips and stumps
Linseed	Shay nuts
Castor beans	Mowrah nuts
Corn germs	Meat scraps
Cottonseed	Bones
Wheat germs	Garbage

Another phase of solvent extraction has been developed departing in some respects from the procedure as above described—namely, treating a wet oleaginous mass with solvent whereby the oil or fat is removed.

equipped with an agitator of some sort. The rotary extractor, on the other hand, is usually a tank shaped like a boiler and mounted to rotate on its horizontal axis, thus avoiding the necessity of an agitator.

STATIONARY EXTRACTORS

In Figs. 1, 2 and 3 are illustrated different types of stationary extractors. In Fig. 1 the system is more like the German development, in which continuous extraction with fresh solvent received special attention, according to the well-known Soxhlet principle. The solvent-oil solution in the still is kept boiling; the pure solvent vapor rises through the vapor pipe and is conducted into the extractor from above, slowly percolates through it and flows back into the recovery tank with oil in solution. Thus the oleaginous material to be extracted is becoming weaker and weaker in oil; the solution in the receiving tank is becoming stronger and stronger in oil. It is stated that this type is not suitable to the installation of large units, batches of one ton presenting the optimum working conditions. Such

⁷U. S. Pat. 1,267,611, May 28, 1918; *Chem. Ind.*, vol. 37, No. 17, p. 519-A, Sept. 16, 1918.

small charges may seem uneconomical, but on the other hand it is urged that a small batch can be more easily controlled, with consequent improvement in performance and quality of product.

In Fig. 2 the units are larger and represent the British type of equipment. The extractor unit may be 8 ft. in diameter and 12 ft. high. An iron plate perforated with $\frac{1}{2}$ -in. holes is placed over steam coils to form a false bottom. Over this is laid a plate with smaller holes, and again over this is placed a screen covered with a coarse textile. Such an arrangement keeps the charge of extractive material from falling into and clogging up the draw-off pipe. A stirring arm may be provided in the form of a curved sweep which rotates on the central vertical axis. Since the sill of the discharging door is almost flush with the floor of the extractor, the rotation of the stirring arm can be used to force out the extracted residue when the extraction and steaming off are concluded. The charging door on the top of the extractor allows loading from an overhead hopper or conveyor.

Fig. 3 shows a type in which during the first cycle the hot solvent is saturated as nearly as possible by repeated percolation of the oleaginous material, but without being evaporated and recondensed. In the second cycle the solvent is boiled off from the extracted oil in the lower compartment of the extraction cell, condensed and run back to the extraction cell, where it accumulates and periodically siphons back to the still below. This is in strict accordance with the Soxhlet principle and results in repeatedly washing the nearly spent material with clean solvent. The periodical siphoning is controlled by a float in the lower compartment containing the solvent. In the third cycle the extract accumulated in the still is concentrated by evaporating off the excess of solvent. The condensed solvent is conducted to the storage tank for repeated use. In the fourth cycle both spent meal and oil extract are freed from solvent by steam.

Plants recovering grease from garbage operate on the extraction principle. Several processes are being used for this purpose, but since this is a field in itself, no detailed consideration is given it here. The problem presents itself as one dealing with a low grease content (3 to 5 per cent) and a large amount of water (about 85 to 90 per cent).

ROTARY EXTRACTORS

A more recent type of extractor has been developed along somewhat different lines. This so-called rotary extractor consists essentially of a horizontal, boiler-shaped tank designed to rotate and provided with charging and discharging manholes. A false head or false

bottom allows the solvent with its content of oil to drain away from the oleaginous charge when the percolator is at rest and to be freely pumped out.

Figs. 4 to 6 illustrate several types of rotary extractors. The plant illustrated in Fig. 4 will handle about twenty-five tons per twenty-four hours. The extractors in Figs. 5 and 6 have free chambers placed above or below, or both, corresponding to a false top and false bottom; if one becomes clogged during the drainage of the solution, the extractor is rotated 180 deg. to use the fresh surface. It is evident that the rotating of the extractor serves to break up any tendency to lumping, channeling, etc. When the solvent has taken up a large amount of oil, the rotation is discontinued to allow ready removal of the oil-solvent solution. In the type wherein a free chamber extends the length of the unit (Figs. 5 and 6), the extractor is stopped in the position where the false bottom is below; in that provided with a false head any

FIG. 2. SECTION OF STATIONARY PLANT OF BRITISH TYPE

position, when at rest, is satisfactory. The solvent-oil solution then slowly drains into the free space within the compartment, whence it is pumped out. A fresh lot of solvent (or preferably one used as a wash in a previous batch) is then pumped into the extractor, and the whole operation is repeated several times until the extraction reaches the point of economic equilibrium—i.e., until there remains so little oil in the charge that its removal is not profitable. In well-operated plants less than 1 per cent of oil is lost in the extracted residue.

Likewise in the process of solvent removal from the extracted oil-free residue (pomace), rotation serves to keep the mass from packing and from allowing the steam to blow through open channels and other free paths of travel.

When the process is complete, the manhole covers are removed and the machine is rotated. At every rotation a large part of the extracted and dried residue

is discharged onto a belt or hopper under the extractor and conveyed to the pomace storage house. The machine is emptied in a few minutes and is then ready for a new charge.

SOLVENTS

One of the most vital factors contributing to the success or failure of the solvent extraction process is that of the kind of solvent used. The issue is not joined so much to the relation between its chemical constitution and the quality of the oil extracted therewith as it is to what might be called the physical or certainly secondary chemical effects. Since these are more or less specific to the several solvents discussed, they will be considered under the respective solvents.

As stated above, carbon bisulphide was the first to be used on a large scale and is even now employed for treating olive residues of low oil content. Such so-called sulphur oil immediately raises in the mind of the trader and user a corroboration of the current discount borne by extracted oil. The technological abuse given the olive pomace before extraction, the more or less faulty equipment and the unsatisfactory solvent are

is a mixture of products with ascending boiling points, varying often from 80 deg. C. (176 deg. F.) to 170 deg. C. (338 deg. F.). When distillation of the solvent from the oil is attempted, the lighter fractions go over first in preponderating amounts. As these are more and more removed, the residual solvent becomes richer and richer in the higher boiling constituents. The result is that the last traces of solvent, which at best would be more or less difficult to remove (as is commonly experienced in removing even ether in laboratory

FIG. 1. SECTION OF ROTARY EXTRACTION PLANT

analyses), are rendered increasingly so on account of the residual fractions of unusually high boiling point. It has been pointed out that the losses of solvent accompanying such extraction are greater in the low-boiling fractions with the result that the whole body of solvent gradually becomes richer in high-boiling constituents, thus raising the average boiling temperature. This is corrected by adding some special low-boiling fractions from time to time. The factors favoring the use of this substance are cheapness and availability.

One of the war-time benefits to industry is the greatly increased production of benzene. It is now sold at prices comparable to gasoline and is produced in such quantity that its availability seems to be assured. It comes on the market in several grades designated by the color and the percentage which distills over at 100 deg. C. The residue consists of mixtures of higher boiling constituents. Consequently, use of such a solvent introduces the difficulties experienced in using gasoline—namely, temperature range of distillation and difficulty of removing last traces of the higher boiling fractions. It seems from theoretical considerations, laboratory tests and factory operations that 100 per cent water-white benzene gives the best general results in so far as the common commercial solvents are concerned. At the present time its use in this country in the extraction of the higher grade vegetable oils is probably greater than that of any other solvent.

NON-FLAMMABLE SOLVENTS

All of these solvents, however, possess great flammability. Carbon bisulphide is declared to be spontaneously combustible under certain conditions. To this must be added a toxic effect on the workmen. The flammability of gasoline and benzene is well known. Accordingly efforts have been made to introduce a

FIG. 3. SECTION OF STATIONARY EXTRACTION PLANT

overlooked. Experience shows that substances containing sulphur more or less loosely combined are exceedingly difficult to remove from products treated with them.

Another widely used solvent in the same category but not quite so difficult to handle is solvent naphtha or gasoline. As is well known, this product is not a single chemical compound with constant properties, but

solvent free from fire risk. The so-called chlorine-substituted hydrocarbons have been found to answer this purpose. Essentially, they are single chemical products consisting of one or more atoms of chlorine substituted for as many of hydrogen in certain organic compounds. Specifically, the more common ones are bichlorethylene, trichlorethylene, tetrachlorethane, pentachlorethane and carbon tetrachloride. All of these are non-flammable and can be made practically constant in boiling point. The last one is a product of widespread general industrial use. Demand has placed some of the others also on the market to a limited extent. It is claimed that these solvents produce a higher grade of crude oil than do ethyl ether, carbon bisulphide, gasoline and benzene, and that such crudes refine to an edible grade more readily than those produced by benzene and gasoline. This is attributed to their selective solvent action in dissolving out the oil and leaving the other accompanying products unaffected.³ However, recent work by Sievers and McIntyre⁴ shows quite plainly that from the standpoint of the quality of finished extracted oil in laboratory tests made in glass flasks there are no facts to indicate the advantage of trichlorethylene and carbon tetrachloride over benzene

tion, protection can be secured by lining the equipment with lead.⁶ Probably better practice is to adopt the method patented by Barstow,⁷ whereby the solvent is passed over a layer of unslaked lime to remove in each cycle the hydrochloric acid formed during steaming. Just how much solvent decomposition takes place is brought out in the following experimental results.⁸ The

cr gasoline, in so far as quality of finished oil is concerned.

Although these properties of non-flammability make the solvents appear ideal, it is also stated that they decompose during the cycle of extracting and steaming with the liberation of free hydrochloric acid. This attacks the equipment and necessitates the use of lead lining throughout. In reply to this it is stated that carbon tetrachloride is the greatest offender and that if trichlorethylene is kept free from the bichloro-derivatives it is perfectly safe from dissociation.⁹ Even if solvents are used which undergo this slow decomposi-

taining 250 g. of solvent and 100 g. of water in an iron vessel having 2 sq.dm. of exposed surface.

It seems that the chlorinated substances do attack the containing equipment, necessitating a relatively expensive lining with lead. Table I gives a list of the principal solvents with their respective properties.⁹

The speed of evaporation of various solvents is frequently of special interest. Table II¹⁰ shows the com-

parative speed of evaporation of the most commonly used solvents. In each case 5 c.c. of each material was allowed to evaporate under similar conditions from an alberene stone dish approximately 4 in. in diameter. The materials tested, other than coal-tar products, were purchased in the open market and therefore represent commercial grades.

The financial advantage of using a solvent with a fairly constant boiling point over one which has a wide

which is non-flammable, will distill off at the lowest practicable temperature, require the least coal, produce the best grade of oil, be cheap, stable and commercially available. No one solvent fulfills all of these requirements. At the present time, practice seems to favor benzene.

ECONOMIC CONSIDERATIONS

It is at once apparent that if the process is at all practicable it points to great economic advantage. The most evident advantage of solvent extraction over pressure is in the matter of yield of oil. When an ordinary hydraulic box press produces cake with 6 per cent oil, it is considered good performance. The average in the cottonseed oil industry for the 1919 season was about 6.4 per cent, as is evident from the analytical reports constantly presented in the cottonseed oil press. The introduction of the cake or curb press is stated to improve on this to some extent, since they are said to

FIG. 6. PLAN AND ELEVATION OF ROTARY EXTRACTOR

temperature range of distillation is brought out by the statement of an operator who has used both gasoline and benzene that about 3,000 lb. of steam per ton of garbage treated would be required to distill off 72 deg. Bé. gasoline, leaving about 2 1/2 gal. in the residue (hence lost), while benzene would require about 2,200 to 2,300 lb. of steam, leaving only about 1 gal. unrecovered. It is to be noted that this estimate is checked by the fact that in the proportions of the heats of vaporization of gasoline and benzene—namely, 130 and 100—there would be required 2,308 lb. of steam for the benzene distillation, assuming that 3,000 lb. of steam were required for the gasoline.

It will be recognized that the best solvent is one

have produced cake as low in oil as 4 per cent. However, this is admittedly uncommon practice. About 6.4 per cent oil in cake can be accepted as representing average practice in the oil industry where hydraulic pressure is used.

To produce a meal by solvent extraction containing 2 per cent oil presents no difficulty whatever. Manufacturers of this type of machinery guarantee meal to contain no more than 1 1/2 per cent oil. It is to be expected that 1 per cent oil-bearing meal is perfectly feasible. From such a non-fibrous, mushy product as castor beans, a pomace can be produced which will average as low as 0.6 per cent of oil.

Table III gives the oil yields by the pressure method

The last column gives some idea of the oil economy in solvent extraction. Note: It is to be noted that the yield of oil cannot be found by subtracting the oil content of cake from that of the seeds, because oil in cake is figured on the basis of cake and not on the original seed.

versus extraction, with the corresponding loss of oil. These figures are recalculated from Merz' table;¹¹ the extraction figures are based on leaving 1½ per cent oil in cake. Fractions less than 0.5 are discarded; those greater than 0.5 are as units.

Another item of particular importance at this time is that of cost of operation. A force of one foreman and two laborers can operate a 50- to 100-ton percolator plant. In fact it is estimated that an overall charge of \$11 per ton of raw material will cover all costs of producing crude oil by solvent extraction in a 50-ton plant, while about \$7.50 per ton of raw material will cover those in a 100-ton plant. In addition to the monetary saving, there is the added advantage of reducing labor to a minimum.

Against these advantages are fire risk, lower grade crude oil and trade prejudice. The first seems prohibitive, but when one considers the great number of pharmaceutical houses, paint and varnish works, explosive plants and last but not least every automobile, regarding which there is no hysteria, the objection pales considerably. A lower grade of crude oil is undoubtedly obtained in some cases (though not necessarily in view of certain recently published work of J. H. Shrader, *Cotton Oil Press*, April, 1921, p. 42). Trade prejudice is indeed to be considered, but is not insurmountable, particularly if the plant procedure is such as to produce a high-grade refined oil. After all, trade prejudice is built on experience; it can be destroyed accordingly.

USES OF PRODUCTS

It is often and persistently stated that products (oil and meal) obtained by solvent extraction are not comparable with those yielded by expression. Such statements are only partly correct. There is no doubt that solvent extraction has produced oil and meal of low grade, evidenced by high color and traces of solvent. But it is also true that extracted products have been produced free from such objection. The operator of the extraction plant of a large linseed oil company stated that in the years of his service he never received a single complaint of solvent in his meal. It is moreover true that extracted oils may be darker in color than expressed oils, but these can often be refined to comparable grades indistinguishable from expressed standards.

Heretofore the chief rôle of the solvent extraction

plant in the vegetable oil industry has been to work up off-grade residues, damaged seed, leather scraps and other materials of little or no other value than their fat content. Not much attention seems to have been devoted to giving the products any other outlet than what they can readily find in competition with other admitted low-grade commodities. The oils go to industrial uses (paint, soap, etc.); the meal mostly goes to fertilizer. In Europe, however, these extraction products are used for human food. In this country the meal is beginning to find a market as stock feed. If history repeats itself (we seem almost always to follow European practice) we shall follow Europe in finding ways to prepare even the oil for food.

Classification of Lead Production

Sub-committee I of the Society for Testing Materials' committee on non-ferrous metals and alloys reports as follows on the available supply of pig lead:

For the ten years ended Dec. 31, 1920, the production of pig lead in the United States from foreign and domestic ores averaged 559,000 tons per annum. This production can be divided into the following classes:

DOMESTIC		Tons
Desilverized (corroding and common desilverized).....		273,000
Southeast Missouri (chemical lead).....		176,000
Southwest Missouri (soft Missouri lead).....		33,000
Antimonial lead (not covered by these specifications).....		16,000
Total.....		498,000
FOREIGN		
Desilverized.....		58,000
Antimonial.....		3,000
Total.....		61,000
Grand total.....		559,000

Corroding Lead.—The greatest use for pig lead in the United States is for the manufacture of paint pigments. As the production of low-bismuth corroding lead is insufficient to fill this demand and as there are consumers who prefer low-bismuth corroding lead for purposes other than the manufacture of paint pigments, corrodors to obtain the benefit of a broad market should take quotations on both grades of corroding lead.

Chemical Lead.—Of the southeast Missouri lead ore from which chemical lead is produced about one-third is refined by the Parkes process and thereby made into a high-grade low-bismuth corroding lead 99.99 per cent pure. More than 100,000 tons of chemical lead is used annually by the manufacturers of acid-resisting sheet lead, storage batteries, lead-encased cable, lead pipe traps and bends, etc., and in the Central Freight Association territory, where the freight rates are favorable to users of common lead.

Soft Missouri Lead.—The production of this grade is comparatively small, and its use is largely confined to the St. Louis and Chicago districts.

Desilverized Lead.—As all grades of lead are desilverized with the exception of chemical and soft Missouri lead, this class would cover all other grades of lead not pure enough to be sold under corroding specifications.

Chemical specifications for pig lead in the tentative standards now specify for both low-bismuth and high-bismuth corroding lead, as follows:

Element	Low-Bismuth Corroding Lead Per Cent Not Over	High-Bismuth Corroding Lead Per Cent Not Over
Bismuth.....	0.0050	0.0500
Silver.....	0.0015	0.0010
Copper.....	0.0015	0.0010
Copper and silver together.....	0.0025	0.0015
Arsenic.....	0.0015	0.0015
Antimony and tin together.....	0.0095	0.0060
Zinc.....	0.0015	0.0015
Iron.....	0.0020	0.0020
Lead (by difference).....	99.9780	99.9375

Frederick Fraley Sharpless, Secretary, A.I.M.E.

IF THERE is anything in name and antecedents the directors of the Institute did well in selecting Frederick Fraley Sharpless to succeed Bradley Stoughton as secretary of the American Institute of Mining and Metallurgical Engineers.

Born in West Chester, Pa., of good old Quaker stock, his early days were spent on the farm on the Brandywine, in the center of Revolutionary battlefields. The companionship of his father, an able mineralogist, the gathering of a collection of his own of no mean proportions from the inexhaustible riches of Chester County and the enthusiasm of an Ann Arbor graduate serving as an instructor of sciences in the normal school of his native town filled young Sharpless with a desire to study chemistry.

Columbia and Tech. were beyond his means, but the generosity of Michigan rendered possible the study of chemistry at Ann Arbor. Studying under such men as Prescott, Cheever, Pettee, and Alexander Winchell, and a summer with Theodore Robinson and F. A. Emmerton at Joliet, it was no wonder that the students of chemistry absorbed some of the enthusiasm of these men, and the belief that chemistry would eventually be regarded as an indispensable asset to metallurgy, geology, mining—in fact many and diverse branches of industry.

Upon graduation (1888) Mr. Sharpless went with the late Dr. M. E. Wadsworth to Houghton as instructor and later became professor of metallurgy, ore dressing and assaying.

The students of those days—our associates of today—have not forgotten his lessons in stoichiometry and furnace reactions, which modern chemists tell us were all wrong in spite of the way the equations balanced and the metal ran out of the tap hole.

Mr. Sharpless became a member of the Institute in the year 1889, and was one of the members visiting Europe as the guests of European mining engineers that year. Referring to the records of the Plattsburg meeting of the Institute in 1892, as recorded in the *Transactions*, it will be noted that Mr. Sharpless was married in June of that year, and that a reception for him and his bride was one of the features of the meeting. Dr. Raymond, making the presentation speech, gave him some sound advice, which possibly is responsible for his good standing with the members of the Auxiliary. The lines the doctor spoke in handing some silver spoons to the bride were:

Take then these trifles, may they teach a golden truth
in silver speech;
That as the years of wedlock run, the days of spooning
are not done.

Leaving Houghton in 1892, he opened a chemical laboratory in Minneapolis in association with H. V. Winchell. Winchell gathered the samples, Sharpless made the analyses and assays, but it was not long before questions in regard to mine and mill operating began to come thick and fast. Since the business had developed in an unanticipated direction it was evident that a part of his education had been neglected. He therefore proceeded to remove the deficiency and become acquainted with operating details in the mine and smelter. The laboratory was closed and Sharpless went to work as a miner and mill hand on the Mother Lode, where Richard A. Parker and W. L. Honnold were

conducting extensive exploration work. Two or three years' strenuous work from Coulterville to Angels Camp gave him the experience that he had previously lacked. From this College of Hard Knocks he graduated to accept the management of the California Copper Co. A furnace at Madera was operated until it had smelted all the ore in its own mine, and all that it could beg, borrow, buy or steal from its neighbors.

From 1900 to 1912 Sharpless was a wanderer, traveling, reporting, exploring and operating for English principals, chiefly as American representative of the Consolidated Mines Selection Co. of London and its affiliated organizations. This work took him to British Columbia, the Yukon, Alaska, to many parts of Mexico, into Salvador, Honduras, and South America, where his mining experience was interesting and profitable and

where his political experience rivaled that of Richard Harding Davis. Two years in Colombia familiarized him with mining possibilities of that country, and was followed by the investment of considerable English capital in substantial mining ventures. Only one who has lived the life can know much of the continued interest in new scenes, the examination of operating and abandoned mines, near mines and prospects.

A season was spent in Asia Minor, where the mercury resources were investigated, two properties were bought, equipped with Scott furnaces and placed on a producing basis. One of them was a pronounced success, and during the World War the Turks found it quite serviceable. Another season was spent in the bush on the West Coast of Africa, in mining examination and in fighting malaria, yellow fever and various other microbes which make life interesting if not enjoyable in that country. Sandwiched into these in-

Photo by Pach

FREDERICK FRALEY SHARPLESS

vestigations was a trip to Dawson. It occurred in the spring preceding the visit of Beatty and Perry, and Sharpless spent a month looking over the field with the idea that many of the frozen placers could be worked by modern dredges—thus having the same thing in mind which they later took up. While Sharpless was of the opinion that such a venture would eventually prove profitable, he advised against tying up for a long time the immense amount of money involved, pending the acquisition of reasonably accurate data on the returns which would be secured.

For the past eight years Mr. Sharpless has had an office in New York where he has been employed in consulting work, visiting many of the mining districts through the United States, Mexico and Canada for American clients. For three years he was secretary of the Mining and Metallurgical Society of America, and at all times he has given freely of his time to that class of the engineer's work which brings no emoluments except the satisfaction of knowing that one has done a work that was worth the doing.

Note on Alloying Tellurium With Some White Metals

BY J. H. RANSOM AND C. O. THIEME

IN A mimeographed article recently received from the Solder and Bearing Metal Manufacturers Association the secretary, as a result of his observations at the National Chemical Exposition, called attention to the appearance of tellurium and suggested its use as a hardener of lead, and, perhaps, of other metals. Since the writers had already undertaken a study of its action on lead and other white metals, it seems of interest to record these results in a preliminary note in order that others interested in investigating the subject may have before them such facts as have been obtained.

The tellurium used in this investigation was obtained from Superintendent A. E. Hall, of the American Smelting & Refining Co., Omaha, Neb., to whom we express thanks.

The first experiment with tellurium was carried out in an attempt to use it instead of sulphur in removing copper as an impurity from 50:50 (tin:lead) solder. The solder was made to contain 0.45 per cent copper; 163 grams of the solder was melted and to it was added 0.9 g. of tellurium, 0.733 g. being the amount necessary to combine with the copper present to form cuprous telluride. As soon as the tellurium touched the solder it burst into a glow and then seemed to form hard lumps which only slowly, and in part, disappeared. After stirring the molten mass for some time, during which a dross collected on the surface, the metal was poured to form a number of buttons. The dross was then heated to a higher temperature, when it burned to a yellow powder insoluble in both dilute and concentrated nitric acid and in a concentrated solution of sodium hydroxide. This would indicate that the insoluble residue is not tellurium oxide. On heating some of the yellow powder on charcoal before the blowpipe, the color was somewhat changed, but no lead was formed. Its action with concentrated nitric acid was to form a white powder, perhaps metastannic acid. It was not further investigated. Analysis of a button revealed the presence of 0.27 per cent copper, showing that the tellurium had removed nearly one-half of the copper.

In a second experiment 142 g. of the solder containing 0.27 per cent of copper was again melted and 1.5 g. of

tellurium added to the just molten mass. No change in the tellurium was noted, but on heating to a slightly higher temperature the same glowing occurred as before with the formation of large pieces floating on the surface. The pieces partly disappeared after some time. Some of them were removed, powdered, and then returned to the bath. In the powdered form they were nearly white. During heating the molten bath was constantly stirred with a piece of dry, soft wood, and when most of the pieces had disappeared, the metal was poured into molds. The dross weighed 8.5 g. In this case, however, the copper was not removed, but was present in larger amounts than at first, probably due to the fact that the analysis (0.27 per cent Cu) was not representative of the original melt.

TELLURIUM AND LEAD

In order the better to interpret the results stated above a study of the action of tellurium on lead and on tin, separately, was undertaken. First, 129 g. of pure lead was just melted and upon the surface was sprinkled 1.3 g. of powdered tellurium. The tellurium glowed with the formation of large lumps mixed with a powder which floated as a dross. After heating to a higher temperature and stirring with a piece of dry wood, the metal was poured into a mold. It weighed 115 g. and the dross weighed 14.5 g. The lumps were then separated from the finer powder, which latter was a mixture of metallic particles with a yellow, non-metallic powder. The former were hard but somewhat malleable, and they, as well as the metallic powder, contained both lead and tellurium. Tellurium could not be found in the yellow powder and its nature has not been established. The lead was found to contain 0.2 per cent tellurium and had a Brinell hardness of 5.1. The lumps of dross tested 7.5 Brinell, and possessed a more metallic ring than does lead.

TELLURIUM AND TIN

Some pure tin bars were melted and poured, making four chill-cast cylinders. Two of these were used for comparison and the others, weighing 650 g., were heated just to melting. After removing them from the heat, 7 g. of tellurium was added in powdered form and stirred into the semi-fluid tin. The mass was again heated while being stirred. Some solid pieces collected on the surface and there was some solidification around the edges of the bath, though the temperature was far above the melting point of tin. Most of the floating lumps finally disappeared, leaving a dross upon the surface. No glowing was observed. Finally the metal was heated very hot and poured, making two bars. The dross, which included much metal, weighed 22 g. Tests made with

PHOTOMICROGRAPHS OF TIN AND TIN-TELLURIUM
Fig. 1. Matrix: crystallized tin. $\times 100$. Fig. 2. Bright pin-like areas of tin telluride in a matrix of crystallized tin. $\times 100$. Both etched with 10 per cent nitric acid.

the bars in an Olsen testing machine showed that the elongation as compared with that of the bars of pure tin had decreased from an average of 65 per cent to 54 per cent, while the tensile strength per sq. in. had increased from 3,800 to 4,265 lb. The bars were remelted and poured to form buttons for hardness tests and to get samples for analysis. The tests showed that the metal containing tellurium was slightly harder than the pure tin. Two closely agreeing analyses gave an average of 1.12 per cent of tellurium. This element was also found in the dross.

In order to study the structure of the metal containing tellurium, photomicrographs were made from one of the buttons, and for comparison a similar photomicrograph of pure tin. The etching reagent was a dilute nitric acid. As will be seen from an inspection of Figs. 1 and 2, the tellurium causes the formation of a large number of small particles which appear as white dots in the picture. These are probably tin telluride in a matrix of crystallized tin.

TELLURIUM WITH ZINC AND WITH ALUMINUM

Experiments similar to those carried out above were made with tellurium and zinc and with tellurium and aluminum. In neither case were more than traces of tellurium found in the treated metal, most of it apparently remaining with the dross. However, in spite of its absence in the finished products, the tensile strength, in the case of zinc, was increased from 4,955 lb. to 5,510 lb. per sq.in. and in the case of aluminum from 13,840 lb. to 14,810 lb. In the case of zinc the elongation was nil both with and without the tellurium, while with aluminum the use of this element increased the elongation from 18.5 per cent to 28.5 per cent. The hardness was not changed appreciably in either case.

An experiment was carried out in order to determine if any hardening effect would result from the addition of tellurium to an alloy of lead containing 0.5 per cent of magnesium. No increase in hardness resulted, neither was the appearance changed. It is a question whether the tellurium formed a solution or other intimate mixture with the alloy, since one part of the product gave a good test for tellurium with concentrated sulphuric acid, while a repetition of the test with another portion gave negative results. It is probable that magnesium telluride was formed and that it very largely escaped from the molten alloy.

TELLURIUM WITH ZINC-BASE DIE-CASTING METAL

One per cent of tellurium was added to zinc-base die-casting metal and the molten mass thoroughly stirred. Tests made with the chill-cast bars did not show any change in properties due to the presence of the tellurium, except that the metal appeared to be more nearly free from blowholes. In one test the metal showed the presence of tellurium; but in a subsequent test on the same bar no evidence of its presence could be found.

SUMMARY

Only two of the common white metals appear to dissolve tellurium, and these two only in small amounts. Where solution is effected the hardness and tensile strength are increased to an appreciable extent. In all cases investigated it is probable that tellurides of the metals are formed and that these are little soluble in the molten mass.

Note on Schwartz Furnace Atmosphere When Melting Complex Bronzes

BY R. J. ANDERSON AND J. H. CAPPS

In the course of an investigation of the gas atmospheres in aluminum alloy melting furnaces, reported in *CHEMICAL & METALLURGICAL ENGINEERING*, vol. 25, No. 2, p. 54, July 13, 1921, an opportunity was presented to analyze the gases within a Schwartz furnace melting leaded zinc bronze and lead bronze.

A summary of the results of the analyses is given in Table I. Three samples each were taken from the three different heats, and wide variations in the percentages of carbon dioxide, carbon monoxide, nitrogen and oxygen were found. The variations were undoubtedly due to variations in the operating conditions. The last three samples, however, are fairly uniform. Comparing them with the analyses presented in Table VI of the article cited above, it is seen that combustion is more complete; CO₂ being higher, and CO, H₂, CH₄, and oxygen lower in the bronze-melting furnace.

This may be due to the fact that the melting temperature in the case of bronze is considerably higher than should normally be used for light aluminum alloys,

and the method of conducting the firing in the same furnace used for melting these different alloys should be altered for the alloy. Practically, however, the open-flame tilting furnace, when melting light aluminum alloys, is generally run as fast as possible so as to secure a rapid rate of melting.

A temperature of the second lead-zinc bronze noted in Table I was about 1,190 deg. C., while the furnace atmosphere at about 12 m. was 1,210 deg. C.

Conditions in Belgian Zinc Industry

Belgian zinc production in 1920 was 82,960 tons, in comparison with 19,860 in 1919 and 204,220 in 1913.

Only two Belgian plants manufacture lithopone. They are the Société Anonyme des Produits Chimiques de Wilsele, near Louvain, and the Société Anonyme Stella, at Haren, north of Brussels. Their joint annual production is 16,000 tons.

The production of other zinc products is still considerably below the pre-war figures. While 9,118 tons of zinc oxide was prepared in 1913, the figures for 1920 show only 1,500 tons produced.

Air Pollution and Wastefulness

BY FREDERIC DANNERTH

A RECENT decision of the U. S. Supreme Court relating to the gas carbon black industry of Wyoming involves a number of points which affect the chemical industry in general and industrial wastefulness in particular.

It appears that the State of Wyoming (Chapter 125, Laws of 1919) passed an act which prohibits as wasteful the burning and consumption of natural gas for its products without fully and actually applying and utilizing its heat for other manufacturing or domestic purposes. It forbids owners or lessees of gas wells to sell or dispose of such gas for the manufacture of carbon or other resultant products, in the making of which its heat is not so utilized for other domestic purposes. The act limits the prohibition to cases where gas wells or sources of supply are within ten miles of any incorporated town or industrial plant. Infractions of the law will be dealt with as misdemeanors.

The case was originally heard in the District Court of the United States for the District of Wyoming, and the appeal from this decision was argued Oct. 13, 1920, and decided Dec. 13, 1920, Justice McKenna delivering the opinion of the court. The Midland Carbon Co., together with the Occidental Oil & Gas Co., both Delaware corporations, asked that the Attorney General of the State of Wyoming be restrained from enforcing or attempting to enforce the act.

CASE OF THE COMPLAINANTS

The complainants state that they had built a plant in Big Horn County at an expenditure of \$375,000, that they produce 13,000 lb. of gas carbon black per day, and that this is sufficient for making 117,000 lb. of printing ink. They also make out of that gas 1,600 gal. of gasoline per day. The Occidental Oil Co. in the course of its existence has secured mineral leases covering 1,200 acres of proved gas territory within ten miles of the town of Cowley. The company claimed that its rights under the Constitution of the United States were violated by the state law, that the proposed restrictions abolish, ruin and destroy the complainant's business while leaving it open to others to engage in the making of gas carbon black.

The present consumption of gas from the sand is 15,000,000 cu.ft. per day; the decrease in pressure for the last year has been 150 lb.; the present pressure is about 200 lb. In view of these facts, at the present rate of decrease in pressure the field will be exhausted in sixteen months and there will be no pressure to force the gas out of the sand. The present consumption of gas is about 5,500,000,000 cu.ft. per year.

POSSESSION OF THE LAND NOT NECESSARILY POSSESSION OF THE GAS

The court emphasized the fact that "possession of the land is not necessarily possession of the gas," and "the property of the owner of lands in oil and gas is not absolute until it is actually in his grasp and brought to the surface." Oil and gas, like other minerals, are situated beneath the surface of the earth, but for this one point of similarity in many other respects they greatly differ. They have no fixed *situs* under a particular portion of the earth's surface within the area where they obtain. They have the power, as it were, of self-transmission. Therefore in a previous case it

was adjudged that their use by one owner of the surface affected the use of other owners and an excessive use by one diminished the use of others. A similarity of other minerals was rejected, and the analogy between oil and gas and animals *feræ naturæ* was declared. It was hence decided that the power of the state can be manifested for the purpose of protecting all the collective owners, by securing a just distribution, to arise from the enjoyment by them, of their privilege to reduce to possession and to reach the like end by preventing waste.

VERY LOW EFFICIENCY

The process used by the Midland Carbon Co. is merely an incomplete combustion of gases in an insufficient amount of air, the flames from the different jets practically touching cast-iron channel plates. These are suspended over the flames and are moved backward and forward at a very slow rate of speed. The carbon is scraped off the plates into hoppers and carried to the packing houses by conveyors. It has been claimed by expert industrial chemists that the efficiency of the carbon black industry is very low. That the largest yield known to the producers themselves is 1.75 lb. per 1,000 cu.ft. of gas. That it has been chemically determined that 1,000 cu.ft. of natural gas contains approximately from 33 to 45 lb. of actual carbon.

WELFARE OF COMMUNITY PARAMOUNT

The Midland company stated that the money value of the carbon black was far greater than that of the natural gas. In securing testimony for its case it endeavored to show that its customers would be inconvenienced and it would meet with disaster if the supply of gas carbon black should cease. This entirely selfish point of view was given little consideration by the court, for it is generally conceded that the money which any corporation hopes to make out of its enterprise is not more important than the welfare of the community which makes the enterprise possible. The wells of the Midland company are drilled into the same sand in which the wells of the Lovell Gas & Electric Co. are drilled. This latter company furnishes gas and electricity to the town of Lovell. The sand is a "free-flowing sand"—that is, one in which the gas has free access from one part of the field to the other, consequently the gas pressure would be approximately the same at all the wells drilled into it. It was stated that the present consumption of the gas would materially interfere with the supply of gas to the town of Lovell.

STATE MAY DETERMINE IF CONSERVATION IS NECESSARY

The court held in its decision that it is for the state to determine if any conservation is necessary, and if so it also has the right to determine how far it wishes to go in exerting its power. The statute was intended only to prevent the selection of one product whose production tended to exhaust the supply of gas in a very little while.

The decree of the lower court granting an interlocutory injunction was reversed. At this time similar action is contemplated in the State of Louisiana, and it would seem that the passage of a similar law in that state was in order if only to compel attention to the systematic wastefulness of certain American chemical industries. An industrial process carried on with an efficiency of less than 5 per cent is surely worthy of some attention at the hands of law makers.

Notes on the Metallurgy of Calcium*

Survey of the Development of the Metallurgy of Calcium — Properties and Uses of the Metal and Its Alloys—Detailed Description of the Successful Methods for Preparing the Pure Metal

By P. H. BRACE

Research Laboratory, Westinghouse Electric & Manufacturing Co.

SIR Humphry Davy¹ appears to have been the first to isolate traces of calcium by the electrolysis of moist lime; though while Davy's work was in progress he received a letter from Berzelius and Pontin which described the results of their experiments on the electrolysis of the alkaline earths with mercury cathodes. Davy repeated these experiments and secured amalgams of calcium and the other alkaline earths, confirming the conclusions of Berzelius and Pontin. In 1854 Bunsen² prepared small quantities of calcium by electrolyzing an aqueous solution of the chloride with a mercury cathode and subsequently distilling off the mercury. Matthiesen³ in 1856 prepared small quantities of impure calcium by the electrolysis of a fused mixture of strontium chloride and calcium chloride.

Comparatively little interest was shown in the subject until Moissan,⁴ in 1898, published his results, which showed that nearly pure calcium could be prepared by the reduction of calcium iodide by means of sodium. In the same paper Moissan mentions the electrolytic preparation of calcium from the fused iodide. Moissan⁵ investigated his product with characteristic thoroughness, for a little later in the same year he published an extensive list of the properties of the calcium prepared by the sodium reduction method. In 1898 Bela von Lengyel⁶ gave an account of the properties of calcium prepared in a cell with a porous diaphragm. He reported a purity of 99.2 per cent, and described his product as having a color similar to that of a silver-rich gold alloy. Evidently his metal was contaminated, for the color of pure calcium is silvery-white. Borchers and Stockem⁷ described a calcium cell in which the metal was deposited in the form of a sponge on a water-cooled cathode projecting upward from the bottom of the cell submerged in the electrolyte of fused calcium chloride. A similar cell was used in 1903 by Goodwin,⁸ but he operated at a higher current density and temperature, and so caused the calcium to collect in the molten state and rise to the top of the bath, whence it was removed by means of a ladle. This was a distinct advance over the method of Borchers and Stockem.

Shortly after this, in 1904, Rathenau⁹ made the next noteworthy advance when he used a cathode which just touched the surface of the molten electrolyte, and operated it at such a current density that the surface of the calcium in contact with the electrolyte was kept molten. The cathode was gradually elevated as the metal accumulated, and an irregular rod was thus built

up. This method was commercially successful. Goodwin,¹⁰ in 1904, published the results of a rather extensive series of experiments with an apparatus of the Rathenau type, and gave a rather complete account of the physical properties of the calcium he had prepared. In 1905 Wohler¹¹ reported on his experiments in which an electrolyte containing 100 parts of CaCl_2 and 17 parts of CaF_2 was used. He believed that the low melting point of the above mixture was an advantage, but the experience of others has since indicated that there are disadvantages which more than outweigh the convenience of the low melting point. This will be referred to again in connection with some of the writer's findings.

Arndt¹² described the preparation of calcium aluminum alloys by the electrolysis of calcium chloride with an aluminum cathode. Alloys containing between approximately 20 and 80 per cent of calcium are described, but no particularly useful properties are mentioned.

In 1909 Frary and Badger¹³ published a comprehensive bibliography of calcium metallurgy, followed by a description of the results of their work with the Rathenau form of cell, and in the following year Frary, Bicknell and Tronson¹⁴ discussed the efficiency of the apparatus just mentioned, and concluded that practically 100 per cent current efficiency could be obtained by proper manipulation. They were of the opinion that pure calcium chloride made a more satisfactory electrolyte than the calcium fluoride-calcium chloride mixture of Wohler. At the same time Johnson¹⁵ published an account of a series of experiments with the submerged cathode cell of Borchers and Stockem, and the Rathenau cell; and described the development and operation of a rather novel apparatus in which the metal was deposited on a perpendicular, vertically moving iron ribbon cathode which closed the narrow end of a V-shaped inclosure containing the electrolyte. The wall of the inclosure opposite the ribbon was of graphite, and formed the anode. The cathode current density was kept considerably lower than in the case of the Rathenau cell, and it appears that the calcium was deposited in the solid state, producing a thick plate on the iron ribbon in much the same way as metals are ordinarily deposited from aqueous solutions. The author concluded his paper with an account of the determination of the decomposition voltage of molten calcium chloride, and stated that the value lay between 2.6 and 2.8 volts. In 1909 Cowper-Coles¹⁶ patented a process for the electrolytic preparation of calcium and similar metals, the principal feature of which was the use of a cathode in

the form of a disk whose edge just touched the surface of the electrolyte and which was rotated as the deposit collected.

In 1911 a refining process¹⁷ was described, which had in view the elimination of the included chloride and other mechanically held impurities from calcium produced by the Rathenau and similar methods. In this process the calcium was melted under calcium chloride and collected under an inverted conical iron bell submerged in the molten chloride. The idea was that the calcium would separate completely from the chloride and other impurities by virtue of the differences in their densities.

Moldenhausser and Anderson,¹⁸ in 1913, described experiments with mixed fused electrolytes in which calcium alloys with zinc and some other metals were produced. They also stated that potassium chloride might be added to calcium chloride in amounts up to nearly 25 per cent before the potassium content of the calcium produced became too great to permit the successful working of the Rathenau method. In 1920 the writer¹⁹ published a short account of some experiments on the electrolytic production of calcium, and described a type of cell which he believed to be much easier to operate than the conventional form in which the graphite container for the electrolyte formed the anode. This apparatus will be more completely explained below.

This brief review of the literature will show that almost an even hundred years elapsed after the discovery of metallic calcium before serious attempts were made to prepare the metal in large enough quantities to permit accurate determinations and useful applications of its many interesting properties. Between 1898 and 1910 calcium received considerable attention from the standpoint of both preparation and properties. As a result enough demand sprang up to warrant the commercial production of the metal at Bitterfeld, in Germany. During the last ten years interest seems to have lagged somewhat; indeed, J. W. Richards,²⁰ in 1916, mentioned calcium as one of the well-known and available metals which had not received the extensive application which might be expected from a consideration of its many interesting and unusual properties. Richards pointed out the advisability of closer study of the properties and possibilities of the less commonly used metals, calcium among them. At the present time calcium seems to find such small application that supplies are not regularly carried by dealers, and, furthermore, the prices asked are out of proportion to the difficulties of preparation. It is hoped that this paper may stimulate discussion which will bring out all the present applications of calcium, suggest new ones, and put producers and prospective users on such footing that the interaction of supply and demand will operate to create a good market and a satisfactory supply at prices more reasonable than those which are now obtained.

PROPERTIES OF CALCIUM

The accompanying table gives a short list of the more fundamental properties of calcium. The numbers in the right-hand column refer to the references below.

The following condensed list of reactions may be of interest. The numbers in parentheses following the reacting element refer to the references at the foot of the page.

Carbon (30).— CaC_2 formed exothermically by direct interaction of carbon and calcium metal. Pure calcium carbide is a white solid.

Oxygen (30).—No reaction in dry oxygen at ordinary temperatures. Above 300 deg. C. reaction proceeds rapidly, forming CaO . Takes fire in air if heated above a dull red heat, and burns to oxide and nitride with vivid incandescence.

Nitrogen (30).—No reaction at ordinary temperatures. Slow combination above 300 deg. C. Heated in pure nitrogen at approximately 900 deg. C. the nitride Ca_3N_2 is formed. This nitride is a reddish-brown solid which reacts with water to form ammonia.

Chlorine (30), Bromine (31), Iodine (31).—No reaction at ordinary temperatures if these halogens are pure and dry. Above 400 deg. C. reaction goes on, becoming violent as the temperature is raised.

Fluorine (32).—Reacts violently at ordinary temperatures.

Hydrogen (30).—At temperatures near 700 deg. C. the hydride CaH_2 is formed. This hydride reacts with water and liberates the combined hydrogen, and the calcium remaining then attacks the water and liberates its usual quota of hydrogen. Calcium hydride has been used as a portable source of hydrogen for filling balloons.

Water (30).—Pure water is decomposed slowly by calcium. Hydrogen is liberated and calcium hydroxide is formed. The reaction is greatly hastened by small amounts of impurity in the water.

Carbon Dioxide (33).—At a red heat carbon dioxide is decomposed and the carbon liberated. The oxygen goes to the calcium, forming calcium oxide.

Oxides and Halides (34, 35).—The oxygen and halogen compounds of a number of metals are readily reduced by heating them with metallic calcium. Chromium and manganese are thus readily prepared from their oxides.

ALLOYS OF CALCIUM

The list of calcium alloys that have been prepared and investigated is quite large. The outstanding general properties seem to be brittleness and the tendency to the

formation of intermetallic compounds. Very few of the calcium alloys appear to have any usefulness as structural materials. Aluminum-rich alloys may find application because of their slight advantage in weight over pure aluminum. Lead alloys containing calcium and other alkaline earth metals are finding application as bearing metals for service, such as the usual white metals are put to. The following condensed abstracts will indicate the nature of the work which has been done in the field of calcium alloys.

N. Barr³⁶ has published the results of an extensive investigation of the properties of a number of calcium alloys by the method of thermal analysis. Calcium was alloyed with thallium, lead, copper and silver, and in every case definite evidence of the occurrence of intermetallic compounds was secured.

Moldenhauer and Anderson³⁷ investigated the direct production of calcium alloys from fused, mixed electrolytes. Zinc, aluminum and potassium alloys were made.

Cooper³⁸ has patented alloys of calcium with aluminum, in which the calcium content may be as high as 8 per cent. The claims feature lightness, ductility and ease of machining.

Kroll³⁹ has patented the use of calcium and its light alloys as a filling for hollow steel structural members. He has claimed that, as compared with nickel-chromium steel, structures made according to his patent have the same strength with but 41.56 per cent of their weight.

Hirsh and Aston⁴⁰ experimented with the production of iron alloys, and state that up to 6 per cent of calcium may be alloyed with iron by reducing Fe_2O_3 in gas-tight iron cylinders. They state that calcium destroys the welding property of iron.

Watts and Breckenridge⁴¹ used the brittle alloys of calcium with aluminum, silicon and manganese as reducing agents in the course of experiments on the preparation of some of the more difficultly reducible metals. The brittleness of the alloys was found a great convenience, as it enabled them to be pulverized and brought into an intimate mixture with the substances to be reduced.

Stoekem⁴² stated that calcium dissolved in cast iron with the evolution of considerable heat, and that if considerable amounts of calcium were added a scum of calcium carbide collected on the surface of the molten metal; also that calcium alloys with copper in all proportions, and that some of these alloys are useful as deoxidizers and scavengers in non-ferrous alloys.

Watts⁴³ found that calcium acted as a powerful desulphurizer of molten, low-carbon iron, but that the effect on the phosphorus content was relatively small.

Hackspill⁴⁴ prepared lead alloys by the reduction of lead chloride with an excess of calcium. The alloys were harder and less brittle than lead and tarnished in the air. They were slowly attacked by cold water, and more rapidly by hot water. A crystalline alloy, Pb_3Ca_2 , was isolated by distillation *in vacuo*.

USES OF METALLIC CALCIUM

A summary of the more important uses of metallic calcium is here given:

1. As a reducing agent in the preparation of metals and alloys from their oxygen and halogen compounds.
2. As a reagent in the purification of the inert gases.
3. As a scavenger in non-ferrous metals and alloys.
4. As a scavenger, decarburizer and desulphurizer of ferrous alloys.
5. As a dehydrating agent, as in the treatment of oils and alcohols, for example.
6. As a means of fixing atmospheric nitrogen.
7. As a source of pure calcium carbide by direct reaction with pure carbon.
8. As a stiffening filling for hollow metal structural members.
9. As a constituent of a light aluminum alloy having useful properties.
10. As a hardening component in certain lead-base anti-friction alloys.

PREPARATION OF CALCIUM

There are three general methods for the preparation of calcium, as follows:

1. By the reduction of calcium compounds by metals of the alkali group.
2. By the electrolysis of concentrated aqueous solutions with a mercury cathode.
3. The electrolysis of fused halogen compounds of calcium.

Of these three methods the last is by far the simplest and most direct.

Moissan⁴⁵ is the one who has written most authoritatively on the first method. No advance has been recorded in this direction since the publication of his researches. He discovered that calcium was soluble in molten sodium, but not in solid sodium, and that when calcium iodide and a considerable excess of sodium were heated together in a gas-tight steel container to a temperature of approximately 750 deg. C., the calcium iodide was reduced and the resulting calcium dissolved in the excess sodium, from which it crystallized on cooling in brilliant, silvery, hexagonal crystals. The sodium which was necessarily associated with the calcium crystals was removed by the action of absolute alcohol, which reagent has little effect on calcium. Moissan asserts that he obtained a purity of 99.2 per cent, and from his description of the properties of his product it is certain that it was quite pure.

Calcium may be prepared from aqueous solutions by electrolysis with a mercury cathode. Concentrated calcium chloride solution is the usual electrolyte. The cathode current density is kept fairly high. As the calcium is released it amalgamates with the mercury, and is finally recovered by distilling off the mercury *in vacuo*. Some mercury remains in the calcium even after distillation at temperatures above the vaporization point of the calcium. This method of preparation is obviously indirect and cumbersome.

The electrolysis of pure molten calcium chloride is the most direct and convenient method of securing pure calcium. When properly prepared the impurities will total less than 0.5 per cent, and will consist of included particles of chloride and traces of calcium carbide. Small quantities of calcium may be readily prepared by melting a few grams of dry calcium chloride in a porcelain crucible and electrolyzing with a current of a few amperes, using a graphite anode and a stout iron wire as cathode. Small globules will

collect about the cathode, and may be recovered by shutting off the current and allowing the melt to solidify. The writer has succeeded in building up little rods weighing a gram or so by gradually raising the iron wire as the calcium collected.

SUBMERGED CATHODE TYPE OF CELL

The earlier attempts at large-scale production resulted in the development by Borchers and Stockem of what may be designated as the "submerged cathode" type of cell. Fig. 1 is a diagrammatic representation of such a cell. A graphite shell, *A*, is closed at the bottom by a water-cooled plate, *E*, to which is fastened the upright, water-cooled cathode, *D*, concentric with *A*. The shell and cooling plate are separated by an insulating ring, *H*, of asbestos or mica. Electrical con-

FIG. 1. SUBMERGED CATHODE CELL

A is a graphite shell containing fused calcium chloride, *C*, and forming the anode. The cathode, *D*, is fastened to water-cooled bottom plate, *E*. Calcium collects as at *G*, and rises to surface of electrolyte.

nections are made to the cooler plate and to the graphite shell, as at *F*. The floor of the cell is covered with a layer of powdered calcium oxide or calcium fluoride, *I*.

Operation of the cell is started by filling it with molten calcium chloride and electrolyzing. The calcium collects as at *G*, on the central cathode, and the chlorine is evolved at the inner surface of the graphite shell. The cooler plate maintains a layer of solid calcium chloride, *B*, on the bottom of the cell. The originators of this cell operated it under such conditions of current density and temperature that a sponge of calcium was formed about the cathode. This sponge was compacted by pressing and the chloride removed. The calcium content of the resulting mass was from 50 to 90 per cent. Goodwin worked with this cell in his earlier experiments, and found that much more satisfactory results were obtained by running the cell hot enough to melt the calcium. The globules of metal thus formed rose to the surface of the molten electrolyte, whence they were removed in a ladle and cooled under oil. The writer's experience with this method has been that it will work, but that the product is almost invariably porous and brittle and unsuitable for working into sheet and wire.

THE RATHENAU PROCESS

It appears that the most successful scheme for collecting the calcium as it deposited was developed by Rathenau. He found that a rod of calcium could be built up by using a cooled cathode which just touched the surface of the electrolyte, and operating at such a current density as to keep the surface of the calcium in contact with the electrolyte in a state of fusion while the cathode was gradually moved upward as the deposit accumulated. As successive portions of the electrolyte

were withdrawn from the bath they solidified and formed a foundation for subsequent accumulation. Thus a rod of irregular cross-sectional area was built up. In the usual form of this cell the container for the molten electrolyte was of graphite and acted as anode also.

The writer has worked with a cell of this type, and has found it to be much superior to the submerged cathode arrangement. His experience, however, has been that it was very difficult to get a rod with a cross-section approaching uniformity, and that considerable skill and experience were necessary before one could maintain the cell in operation for any extended period. It appeared that the temperature conditions within the cell were of vital importance, and that they were quite sensitive to changes in the size and position of the areas which were acting as anode. It was conceded that the operator would have much better control of the process if the anode areas were made more definite, and if means could be provided for controlling their size and position. Accordingly, some tentative experiments were then made which showed that the foregoing conclusions were correct, and taught the importance of having the mechanical details worked out with some care and with a view to convenience and certainty of operation.

The arrangement is shown diagrammatically by Fig. 2. The graphite container, *A*, for the fused electrolyte, *B*, was provided with a water-cooled bottom, *C*, which maintained a shell of solid electrolyte, *D*, during operation. A jacket, *F*, of fine graphite and lamp-black protected *A* from oxidation and prevented excessive heat losses. Two water-cooled graphite plates, *G*, *G'*, formed the anodes. These were provided with both vertical and horizontal movement. The cathode, *H*, was water-cooled and provided with gear for raising it steadily at a controllable rate. The continuous current

FIG. 2. IMPROVED RATHENAU CELL

A is a graphite shell, cooled by the water jacket *C*. *B* represents the fused calcium chloride. *G*, *G'* are adjustable water-cooled graphite anodes. *H* is the cathode. Current for electrolysis is supplied from a continuous current generator, *E*, connected as shown.

generator, *E*, could be connected to the cathode and anodes by placing the switch, *S*, in the position shown by the solid lines. It could be disconnected and the anodes made the terminals of an alternating-current circuit by placing *S* in the position shown by the dotted

lines. An ammeter, *Am*, and voltmeter, *Vm*, were connected as shown.

Operation of the cell was started by drawing an alternating-current arc between the tips of the anodes, and melting down enough chloride in the bottom of the cell to form a pool into which the anodes were dipped. After this the molten electrolyte carried the current and was heated thereby. Fresh portions of chloride were added and melted till the bath was brought to the desired volume. Switch *S* was then thrown into the direct current position, and electrolysis started by bringing the cathode into contact with the surface of the electrolyte.

The temperature of the cell while operating was very readily controlled by varying the separation and immersion of the anodes. It has been found most feasible to operate at constant current and to control the conditions of deposition by means of the anodes and the rate of cathode movement. In practice this cell has been found to operate very smoothly, the duration of runs being limited only by the range of motion of the cathode. The diameter of the sticks was uniform to within a very few millimeters, and the quality of the metal such that it could be rolled into rods and thin sheets without any difficulty.

The principal dimensions of a 500-amp. cell are given in the following table:

Container, Acheson graphite.
Out-side diameter, 12 in. (30.4 cm.).
Inside diameter—Top, 11 in. (27.9 cm.).
Bottom, 10½ in. (26.6 cm.).
Depth, 9 in. (22.8 cm.).
Anodes, total workable area, 80 sq.in. (516 sq.cm.).
Average running area, 60 sq.in. (387 sq.cm.).
Working charge of electrolyte, 25 to 35 lb. (11.3 to 15.7 kg.).
Cell voltage, 25 to 30 volts.
Current, 400 to 500 amp.

The best results were usually obtained by running the cell with sufficient energy input to keep nearly the entire charge of electrolyte molten, only a small portion on the sides and bottom of the graphite container remaining solid.

If the cell were allowed to run cool so that thick layers of solid electrolyte formed, difficulty would be experienced when the temperature was subsequently raised, apparently owing to the release of graphite or other impurity which had concentrated in the electrolyte that had solidified during the period of sub-normal temperature. A black scum would form on the surface of the bath, which would react with the calcium being deposited and greatly disturb the delicate temperature balance at the cathode.

When the cell was running smoothly, the layer of molten metal on the lower end of the cathode was approximately ½ in. (0.3 cm.) thick. If the molten zone rose too far, a large globule would break off and float around on the surface of the bath until oxidized or cooled against the side walls. This was a very undesirable happening, as the bath was contaminated by the oxide formed and any metal free in the cell was likely to attack the anodes, disintegrating them and sending finely divided calcium carbide into the electrolyte to contaminate the calcium produced.

It has been found that from 4 to 5 units of chloride are used per unit of calcium produced, while the theoretical ratio is but 2.76 units of chloride to one of metal. The low recovery was due partly to the loss caused by the skimming of the bath which became necessary at times; to the chloride layer which formed on the calcium as it was drawn from the bath; but principally to the atomizing effect of the vigorous evolution of chlo-

rine. A fine spray of electrolyte was formed and carried up the flue by the draft sweeping out the chlorine.

ELECTROLYTES

Of the various electrolytes which have been suggested, the writer has tried calcium chloride-calcium fluoride, calcium chloride-potassium chloride, and pure calcium chloride, and is of the opinion that pure calcium chloride properly dehydrated is the most satisfactory. Both purity and complete dehydration of the electrolyte are essential if trouble is to be avoided in operation.

Satisfactory dehydration was secured by boiling the aqueous solution down with excess of hydrochloric acid and a few per cent of ammonium chloride. The white porous cake formed was broken up, mixed with additional ammonium chloride, and heated out of contact with moist air at 500 to 600 deg. C. for several hours.

Incomplete dehydration was made evident by the evolution of hydrogen at the cathode when electrolysis commenced. Oxygen was apparently freed at the anodes, greatly hastening their disintegration and causing the bath to become contaminated with finely divided graphite. The hydrogen liberated at the cathode interfered greatly with deposition, the graphite was carried to the cathode where it reacted with the calcium, and the net result was a disagreeable mess and little calcium.

If the chloride used for electrolyte contained even small amounts of the salts of sodium, magnesium or aluminum, more or less trouble was encountered, because of the fact that these metals were precipitated along with the calcium, and at some stages of the process so lowered the melting point of the deposit as to make it almost impossible to maintain operation of the cell. When using electrolyte of sufficient purity, a cell could be operated for extended periods with no difficulty and with no need for any change of the electrolyte or additions to it other than the fresh material needed to replace that used up.

The powerful reducing action of calcium was well illustrated by the fact that globules of calcium which became detached from the cathode and remained in contact with the molten electrolyte for some time picked up magnesium, aluminum and sodium from the molten electrolyte. Buttons containing several per cent of these metals have been taken from cells which have been in operation on electrolytes containing but small fractional percentages of salts of the metals first mentioned. Some of these buttons were so highly alloyed as to be quite brittle, to react but slowly with water, and to have a melting point below a red heat.

In closing it may be said that the electrolytic preparation of calcium is a simple matter if pure, dry calcium chloride is used. By "dry" is meant perfectly dry; the "anhydrous," "c.p." material supplied for drying tubes and similar applications may contain as much as 0.1 per cent of moisture, and other troublesome impurities.

CONCLUSIONS

1. Goodwin and Rathenau made important advances in the technique of the electrolytic preparation, and the "contact cathode" process of the latter has met with commercial success.

2. Certain modifications permitting the control of anode conditions have been introduced by the writer, and it is believed that marked advantages result.

3. Pure calcium chloride, completely dehydrated and free from calcium hydroxide, is a most satisfactory electrolyte.

Multiple Effect Evaporation

Discussion of the Multiplex Film Evaporator as Regards Features of Construction and Operation—Development of Evaporator Design Since 1885—Comparison of the Multiplex With Other Types

BY BURTON DUNGLINSON

WHERE evaporation is carried out on an extensive scale, economy of heat is a fundamental factor in the efficiency of the apparatus. In a vacuum-evaporating problem it is obvious that there will be no economy of steam for evaporation if a single-effect vacuum evaporator is used, as the lowering in boiling point of the liquid due to vacuum does not conserve sufficient energy to compensate for the energy used in driving the vacuum pump plus the radiation losses. The only reason single-effect vacuum evaporation is resorted to is the fact that low-pressure exhaust steam can be used to advantage and where delicate liquids are being handled the lowering of boiling point prevents decomposition which would occur at higher temperatures.

Multiple-effect vacuum evaporation was introduced with a view of conserving as much heat as possible by utilizing the latent heat of condensation of the steam evolved from the various vessels. Thus, in a quadruple-effect evaporator exhaust steam can be used for heating the liquid in the first effect. The process of evaporation centers on the temperature difference between the heating medium and liquid to be heated. This is obtained in the first effect by a slight vacuum created by the pump above the liquid and the higher temperature of the exhaust steam used as a heating medium. If the evaporated steam being evolved from the liquid in the first effect is to be utilized as a heating medium in the second effect, it is clear that there must be a sufficient temperature difference between the liquid coming from the first effect and the steam being evaporated from same. The temperature difference is obtained by creating a larger vacuum over the liquid in the second effect, and a similar procedure is followed for the third and fourth effects. The actual vacuums usually desired are: First effect, 2 in. mercury; second effect, 6 in. mercury; third effect, 14 in. mercury; fourth effect, 28 in. mercury.

SYSTEMS EMPLOYED

This system of multiple evaporation (as well as any other system) allows the available heat of evaporated water, as steam, to be utilized to advantage. Theoretically, if radiation losses and other factors did not interfere with the laws, one drop of water during process of evaporation should produce just the same amount of heat as was originally transmitted to heat it up to boiling point and complete evaporation. The energy contained in this steam, if transmitted to another drop of water while being cooled to its original temperature, would be sufficient to evaporate another drop of water under the same conditions and so on *ad infinitum*. Unfortunately this theoretical condition cannot be approached in actual practice, as radiation losses are unavoidable and the condensed steam usually

passes away as hot water and retains a fair number of heat units.

The nearest approach to theoretical conditions would be the use of the largest numbers of multiple effects possible with due consideration to mechanical operation and costs of installation. Sextuple-effect evaporators are known but are very rarely used. Their use is confined mainly to processes in connection with soap and paper manufacture, and this applies also to quintuple effects. It is questionable whether the increased efficiency due to the greater heat units developed in 1 lb. of steam compensates for the extra cost of installation and operation in these styles of evaporators.

Quadruple-effect evaporators are quite common in industry, being used mainly in connection with sugar plantations and refineries, where very large quantities of liquids are handled. Triple-effect evaporation is generally used for most operations where liquids have to be concentrated from a density approaching water to 30 deg. Bé. (sp.gr. 1.26) or thereabouts. This type of apparatus is generally accepted as being the "happy medium," where initial cost, floor space, operating costs and economy counterbalance one another.

GENERAL DEVELOPMENT OF APPARATUS

The development of evaporator design has been very gradual and up to recently has been marked by no decided revolution. From the inception of the jacketed pan to the vertical and horizontal tube evaporator no epoch-making devices were introduced. In fact, it is quite a common practice today to evaporate milk and some food products in a steam-jacketed pan, with addition of coils, to permit perfect cleaning after each run. Naturally the efficiency of such equipment is very low, when compared to the tubular evaporator, which maintains a more rapid circulation.

The standard tubular evaporators are built to operate on two principles: One in which the liquid to be heated circulates through the tubes, and the other in which the liquid to be heated is circulated around the tubes. From a standpoint of easy cleaning and general efficiency the evaporator which permits the liquid to circulate through the tubes is the more acceptable.

When a liquid is heated, convection currents are set up, which ultimately produce circulation. This circulation would be impeded by the formation of steam and dissolved air bubbles if means were not introduced for a fairly violent agitation to free these "insulators" from the tube walls. This is accomplished by introducing one or more wide-bore circulating tubes, through which the liquid passes downward. It is a most natural phenomenon, as the heat transmitted through a narrow-bore tube is much greater per unit cross-sectional area than that through a wide-bore tube, hence creating a temperature difference between the liquid in the nar-

row- and wide-bore tubes. Thus the direction of flow is maintained in a positive way by ascending the small-bore heating tubes and descending the wide-bore circulating tubes. Most standard evaporators have the heating elements of tubes about 2 in. in diameter.

Arguing as above, tubes of narrower bore would be expected to transmit more heat per sq.ft. and maintain a much more rapid circulation, and this has proved to be the case in actual practice. A wide-bore tube evaporator, the usual standard type of plant, with 2-in. tubes, must have a greater diameter than a machine of same heating surface using tubes of smaller diameter. It is also plain that with the former type of evaporator, owing to the absence of any separating device for the steam and liquid adjacent to the top tube plate, a greater free space must be allowed for complete separation of liquid drops from the steam, which would otherwise be carried over to the condenser and wasted. To make doubly sure of this important point, a vapor baffle piece is usually embodied in the head of the evaporator.

ELEMENTS OF DESIGN

The four elements constituting a complete evaporator are: (1) The nest of heating tubes, commonly called a "calandria" and embodying the shell and tube plates. (2) The bottom plate, in which the liquor discharge pipe is fixed. (3) The vapor space or section, usually called the "belt piece," which in a standard evaporator must be of sufficient height and volume to prevent entrainment of foam and drops. (4) The vapor and drop separator or "save-all," which is embodied in the design of the cover plate. This is usually an inner and an outer pipe, which change very quickly the direction of flow of the vapors and result in the trapping of any entrained drops, which pass back to the liquid being evaporated, before the vapors travel to the next vessel or to the condenser. This design embodies all types of vacuum evaporators, and the modification, improvisation and disposition of the contained parts cover the patent types of equipment.

STEAM CONSUMPTION

Steam consumption in most standard types of evaporators varies very little for the different designs and the following evaporating figures will serve as a guide to actual practice. Per pound of steam used, the quantities of water evaporated will be:

In a single effect vacuum evaporator,	0.8 lb.
" " double " " "	1.6 "
" " triple " " "	2.7 "
" " quadruple " " "	3.1 "

The heat losses met with are usually due to: (1) Radiation from the large surfaces of calandria, belt piece and connecting vapor pipes; (2) hot condensed

FIG. 1. CROSS-SECTION OF ONE EFFECT MULTIPLEX FILM EVAPORATOR

water passing to vacuum pump, and (3) bad transmission of heat, due to sluggish circulation and consequent incrustation of tubes with deposits from liquid being evaporated.

Efficient condensation is a prime factor in maintaining a high vacuum on the apparatus and it will be readily understood that the more complete the condensation the smaller sized vacuum pump that will be required. For given quantities of liquids treated in a single, double and triple effect, the size of the vacuum pump and condenser will be cut down according to the increase in the number of effects. The liquid under treatment is usually carried from one effect to the other by means of the different vacuums operating in the vessels. A liquor-withdrawing pump is required to discharge the concentrated product from the last effect.

COLOR OF LIQUID

The conditions operating on the last effect in a standard triple-effect evaporator are not conducive to production of a good colored product, free from contaminated decomposition bodies, because to obtain the necessary heat transmission there must be sufficient liquor present at all times to cover the tubes. This means a fair volume of material which must always be present at the finished density, and consequently there will be a prolonged heat-treatment of a large proportion of the liquid. In most cases the time of contact in a standard single- or triple-effect evaporator varies from one to ten hours according to the required density, and as the liquid is in constant though sluggish circulation most of the time, it is subjected to heat-treatment which is detrimental to the finished product, unless particularly high vacuum is maintained together with the use of exhaust steam having a very low pressure.

EXPERIMENTAL WORK

With the desire to eliminate these undesirable factors, experiments were made with a view of increasing the velocity of the liquid in the heating tubes and so determining the time of contact desirable, in the form of a thin film; producing the concentrated product and if possible removing all liquid immediately this concentration is reached. The first practicable plant to produce these results was of the Kestner type, and the design of this plant in the main has not altered materially from its inception. The tubes of this evaporator are about 1 in. in diameter and are not less than 20 ft. long. It will be seen that with such a long tube mechanical difficulties are likely to be encountered, such as sagging of the tube due to its weight and consequent strain of the top tube plate, with the result that leaks will develop.

Owing to the enormous head room required for the plant a triple-effect evaporator must be composed of three single-effect units extended over large floor space with interconnection vapor pipes, and the time of contact with the 20-ft. tube is extremely large, although film evaporation will reduce the deterrent effect of the heating medium to a minimum.

For quite a number of liquids it has not been possible to employ multiple-effect apparatus, because materials which are sensitive to a high temperature could not be evaporated in such equipment without suffering injury, as the operation of a multiple-effect evaporator, say of the triple-effect type, requires evaporation temperatures calculated from the vacuums employed, and

actual readings on a large scale, up to about 176 deg. F., and if a larger number of effects is used, still higher evaporating temperatures are required.

For small or medium quantities of liquid and where the work performed is more or less intermittent, the use of a multiple-effect evaporator is precluded because of the time occupied in starting and stopping the apparatus. The large floor space required and the comparatively high first cost compared with that of a single-effect evaporator and many other disadvantages to be overcome caused experimental work about ten years ago to be directed to mechanical efforts toward a film type of evaporator with a short tube, which, by reason of its construction, would allow three effects to be superimposed, thus utilizing no more floor space than is required for single-effect evaporator and at the same time so calculating the head room that a barometric discharge condenser could be employed if so desired.

Such an evaporator required an immense amount of detail work in design and experiments under actual large-scale conditions before the desired result could be obtained. It was found that although a thin film of liquid was induced through scientific distribution of steam, no foam was experienced until the liquid left the tubes at very high velocity.

MULTIPLEX EVAPORATOR

This mixture of liquid, foam and evaporated steam required some mechanical device to insure complete separation and experiments resulted in a type of foam separator which arrests the high velocity of the liquor and steam and gives a quick change of direction with consequent complete separation. Even with this new type of evaporator, called a "Multiplex," high temperatures in the first effect could not be avoided, but in consequence of the special construction the quantity of liquid contained in each separate effect and under treatment at one time is so small that the liquid remains in the tubes only one to two minutes as a maximum, and is then drawn off immediately after passing through the foam separator into the next effect, which is at a lower temperature, owing to the higher vacuum being maintained.

It will be readily understood that owing to the high velocity and short distances the liquid has to travel through the tubes, not more than 6 ft., the time of contact is exceedingly short. The effect of high temperature is instantaneous with consequent high-grade product and maximum evaporation owing to the formation of film inside the tube.

A very important development in connection with these high velocities obtained in film evaporation is the scouring effect of the liquor passing through the tube, which has been found to prevent formation of scale or other bodies which would result from prolonged heat-treatment. In fact, an experience over six years in the treatment of a very sensitive liquid has shown the heating tubes to be absolutely bright and clean and free from any foreign deposit.

Most liquids will stand the temperatures encountered without suffering practically any injury, and their quality is affected only when the high temperatures act on them for a considerable time. This explains why, notwithstanding the high temperatures met with in the first effect, no deterioration of the quality of the liquid concentrate takes place in the Multiplex type.

The mode of operation is very simple, the apparatus

being set to work by putting the air pump in action and setting the various liquor and foul air valves distributed on a working platform from an angle of 90 deg. The vacuum sucks in the liquid which is to be concentrated through a control valve and pipe coupled to the feed tank, and the concentrated liquid is ejected continuously through a discharge pipe.

The degree of concentration is controlled by the volume of liquid introduced and the achievement of making a direct and immediate concentration from the strength of liquid entering the apparatus to the finished product will be considered unique. Once the valves have been set and the apparatus is operating, it will work continuously without any further attention.

Fig. 1 shows cross-sectional view of one effect of this Multiplex-film evaporator, and Fig. 2 will show triple-effect evaporator with three of these effects superimposed. This evaporator is complete with surface condenser and plunger type of vacuum pump. The apparatus is absolutely complete, with its feed tank, liquor discharge pump and accessories, and it will be noted how extremely small is the amount of floor space taken up. Its operation is described thus:

When the apparatus has been exhausted of air, the liquid to be concentrated enters through a pipe coupled to the feed tank into a double jacket, where it rises to a uniform height in the tubes, which are surrounded with steam entering through the valve. The liquid very soon gets into ebullition and gives off steam and its contained permanent gases. In the lower part of the heating tubes the steam itself forms bubbles, and as these bubbles are surrounded by the liquor while the steam volume is increasing constantly due to the heat contact, the liquid very soon forms a stream of increasing velocity. The bubbles tend to travel toward the center of the tube, and as a result of this the liquid attaches itself to the tube walls and the steam acts as a carrying medium, driving the liquor further up the tube and still in contact with the tube walls.

The middle and upper parts of the tubes are, therefore, no longer filled with liquid and the tube walls are still wet with it traveling at a high velocity. The bubbles of froth formed in

the lower part of the tubes are broken up so that the liquid leaving the end of the tubes in the form of drops meets the foam separator, where change of direction results in the separation of the liquor and steam. The velocity of the steam between the foam separator and tube outlet is so great that the drops do not have sufficient time to fall, but are blown toward the separating device, where the liquid settles to the floor of the vapor space in the evaporator and thereafter rises through a liquor-conducting tube which communicates with the next vessel maintained at a higher vacuum.

FIG. 2. COMPLETE ARRANGEMENT OF TRIPLE EFFECT MULTIPLEX EVAPORATOR

FIG. 3. COIL TYPE VACUUM PAN, 12 FT. DIAMETER.
MODEL OF 1885

The vapor from the first effect rises to the second heating compartment and there serves as a heating medium and the liquor passes into the next effect, where the process of evaporation is repeated in the same way as in the first effect, with the same separation and treatment in the third effect, from which the liquor is drawn off after it has passed through the evaporator only once and has been concentrated to the desired degree. The vapor from the last effect is conducted by means of a vapor pipe to the condenser maintained under vacuum by means of the pump.

MECHANICAL ARRANGEMENT

The simplest way of arranging the effects in this type of film evaporator is to place them one above another, and this can be done for all ordinary problems, but where large quantities of liquid have to be handled it may be advantageous to arrange the effects alongside each other, although the floor space taken up is much smaller than that required for a standard evaporator.

As already pointed out, owing to the mechanical construction, the liquor cannot rush through the tubes in the form of froth, as it very soon adheres to the tube walls in a thin layer and evaporates further without being impeded by formation of froth and pockets resulting from the release of uncondensable gases. These last two factors interfere very much with evaporation in ordinary types of evaporators, and this explains why much greater efficiency can be obtained in the film type of apparatus. The central entrance of steam into the heating space causes and maintains an energetic circulation, so that all the heating tubes are heated with the utmost possible uniformity and no pockets are formed in which deleterious gases can collect.

For liquids which are sensitive to the influence of temperature, such as glue, tanning materials, food products, etc., the apparatus is constructed in such a way that the whole amount of liquid contained in contact with the heating surface in the apparatus is only a few gallons. Every particle of liquid that remains, therefore, is only a few minutes in the apparatus and is then forced up by the liquid following it.

COST DATA

To permit of comparison as to the actual saving in multiple-effect evaporators over single-effect, working

balance sheets have been drawn up. The cost figures stated have only been estimated and the capacity of the apparatus is, in each case, assumed to be ten tons, or 20,000 lb., of water evaporated in ten hours. The cost per ton of steam is taken at \$0.15 and the cost of 32 cu.ft. of water at \$0.005 and the cost of one horsepower-hour at \$0.01.

1. Single-Effect Vacuum Evaporator, Ordinary System		
Steam consumption, 20,000 lb. at 1.05 = 10.5 tons at \$0.15		\$1.57
Water consumption, 10 tons $\times$ 25 = 250 tons at \$0.005		1.25
Power required, 5-hp. 10 hr. = 50 hp.-hr. at 1c		0.50
Cost of evaporating 20,000 lb. of water daily		\$3.32
2. Triple-Effect Multiplex Evaporator:		
Steam consumption, 20,000 lb. at 0.4 = 4 tons at \$0.15		\$0.60
Water consumption, 10 tons $\times$ 10 = 100 tons at \$0.005		0.50
Power required, 2 hp. 10 hr. = 20 hp.-hr. at 1c		0.20
Cost of evaporating 20,000 lb. of water daily		\$1.30
3. Quadruple-Effect Multiplex Evaporator:		
Steam consumption, 20,000 lb. $\times$ 0.3 = 3 tons at \$0.15		\$0.45
Water consumption, 10 tons $\times$ 7.5 = 75 tons at \$0.005		0.37
Power required, 2 hp. 10 hr. = 20 hp.-hr. at \$0.01		0.20
Cost of evaporating 20,000 lb. of water daily		\$1.02

DEVELOPMENT OF EVAPORATOR DESIGN

The original evaporators, utilized on a large scale for the production of concentrated commodities, were coil pans of beautiful design and artistic curvatures; all hand made and polished to give the machine a pleasing appearance. It must be remembered that at this time, from about 1812 to 1885, there were no drawings used in the workshops. The drafting room was unknown and reference to Fig. 3, showing the 12-ft. diameter copper vacuum pan, made in 1885, will show that there is a decided absence of corners and an avoidance of perpendicular sides, in order to maintain a gradual change in velocity of the vapors, thus cutting down frictional resistance. In those days the prevailing opinion was that sharp curves interfered with the operating of the pan and therefore any modification in the design which would tend to influence the results was discarded.

It will be noted that there is an extremely large space for the liquor with a comparatively small vapor space and only coils were used for heating. The general design is made with a view of facilitating manufacture rather than a scientific basis for efficient operating. Evidently no calculations were made as to the yield of vapor, and the change of direction in flow of this vapor,

FIG. 4. STEAM-JACKETED VACUUM PAN

for the prevention of entrainment, simply depended on a baffle plate which was included in the external save-all—this being furnished with a return pipe leading to the evaporator.

MILK EVAPORATING PANS

The semi-spherical bottom was evidently included to facilitate complete draining of the concentrated liquid. While the steam-distributing arrangement, comprising header, angle valves and pipes leading to the various coils, is primitive, the solid, rugged, artistic design of this evaporator would insure long life but extremely low efficiency. The present milk pans, as shown in Fig. 4, do not depart much from the above basis of design.

FIG. 5. COIL TYPE VACUUM PAN WITH JET CONDENSER

There is the same contour, with lengthening and widening of the vapor space and an elongation of the dome, with a more scientific application of the save-all for entrainment. The heating arrangements are still of the coil type, supplemented by a steam jacket, the probable reason being to prevent any corners where material would deposit.

One essential feature which influences the design of pans for food products is the rigidly enforced law that there must be no cavities or projections which would not be easily accessible, as the interior of the pan must be cleaned thoroughly

after every run. Otherwise any depositions would eventually become the breeding place for bacteria, which would destroy subsequent charges. These pans are usually of strong and substantial make, consisting of a steam jacket or casing, mounted on columns, fitted with inner copper bottom suitably flanged and joined to the jacket by means of wrought-iron rings, secured by screw bolts and nuts. The head of the evap-

FIG. 6. COIL TYPE VACUUM PAN WITH BAROMETRIC DISCHARGE

orator is usually constructed with a view to avoid losses through the vacuum pump.

COIL EVAPORATORS FOR SUGAR

Coil vacuum evaporators were admirably adapted to the concentration of sugar juices, and as the quantity of this liquid is large special arrangements had to be made for the handling of mammoth quantities. It is common practice to use a coil pan, or combination of a coil and tubular heated pan, for sugar juice. The reason has never been clearly explained or analyzed but appears to be tied up with the production of sugar crystals of a definite size. In evaporating sugar juice it is usual to carry the concentration to a point where an inoculation with crystals will produce crystals throughout the whole mass.

This means that the coil type of pan insures a large body of liquid out of contact with the heating surface (the coils being arranged around the sides and bottom) and thus allows crystallization to proceed uninterrupted. Of course there is also the presence of soluble salts in the juices which deposit on the heating surface, owing to the fact that circulation is sluggish toward the end of evaporation. The coils are easily subjected to inspection and cleaning, thus insuring a popular tendency toward the adaptation of this type of pan for this particular problem.

FIG. 7. VERTICAL TUBULAR CIRCULATING EVAPORATOR

These evaporators are usually made in sizes up to 15 ft. in diameter, and as such a large machine requires a proportionate vapor pipe, means had to be found to modify the existing external save-all, which was a separate piece of apparatus coupled to the dome of the pan. This resulted in the development of an internal save-all, comprising an integral part of the evaporator. Fig. 5 shows a general arrangement of such an evaporator with a jet condenser and wet vacuum pump, while Fig. 6 shows the same evaporator with a barometric condenser and dry vacuum pump.

As industry developed there were demands for an evaporator of large heating surface, low floor space,

large vapor space and an arrangement whereby the crystals deposited during evaporation could be removed without interfering with the process. The tubular evaporator was therefore developed in both the horizontal and the vertical type, having much greater heating surfaces per square foot of floor space than the coil type. The large vapor space was made to contend with the heat-treatment of the liquids which are apt to foam under vacuum, and the internal save-all device was also embodied in such a design. It will be noted how the tendency of design is toward an increased height with proportionate diameter. Such an evaporator is used almost universally for problems where crystals are deposited during the process. A cross-sectional view of this type of evaporator is shown, minus the "salt pot," in Fig. 7. The effects are arranged alongside each other, and a comparison with the Multiplex triple-effect evaporator in Fig. 2 will show the important saving in floor space and ease of operation introduced by using this latter machine. The cross-sectional diagram (Fig. 1) shows the method of heating and separation of concentrated liquor from the evaporated steam in the Multiplex evaporator. The accompanying tables show tests of this evaporator handling various solutions.

OPERATING TESTS ON GELATINE LIQUOR WITH MULTIPLEX TRIPLE-EFFECT EVAPORATOR

Construction:	3 superimposed effects, all copper, tinned inside
Weak liquor:	In at 0.2 deg. Be. } 84 per cent evaporation
Strong liquor:	Out at 6 deg. Be. }
Water evaporated:	= 5400 lb. per hour
	= 11 lb. per sq.ft. of heating surface
Steam pressure:	Exhaust steam at 3 lb.
Steam used:	1 lb. per 2.78 lb. of water evaporated
Water in:	80 deg. F. } Surface condenser used
Water out:	110 deg. F. }
Temperature of finished gelatine from last effect = 130 deg. F. at 27 in. mercury vacuum.	

OPERATING TESTS ON MALT SIRUP WITH MULTIPLEX TRIPLE-EFFECT FILM EVAPORATOR

Construction:	3 superimposed effects, cast iron with copper tubes
Weak liquor:	Wort at 4 deg. Be.
Strong liquor:	Out at 28 deg. Be.
Water evaporated:	10,000 lb. per hour
	= 10 lb. per sq.ft. of heating surface
Steam pressure:	Exhaust steam at 5 lb.
Steam used:	1 lb. per 2.8 lb. of water evaporated
Water in:	70 deg. F. } 30 deg. F. rise, using 14,000 gal. per hour.
Water out:	100 deg. F. } with jet condenser and wet vacuum pump
	= 1.4 gal. per lb. of steam evaporated
Temperature of finished malt sirup from last effect at 27 in. vacuum = 126 deg. F.	

EVAPORATION OF ALUM SOLUTION IN MULTIPLEX VACUUM TRIPLE-EFFECT

Weak liquor:	In at 27 deg. Be.
Strong liquor:	Out at 45 deg. Be. at 76 deg. C. (solid on cooling)
Steam pressure:	12½ lb. per sq.in.
Steam used:	1 lb. per 2.78 lb. of water evaporated
Water in:	At 5 deg. C. } 7 deg. C. difference
Water out:	At 12 deg. C. }
Water used:	2½ gal. per lb. of steam evaporated
Note: The solution entered the evaporator at a density which is usually the finishing point for most liquors in a triple effect.	

Microscopic Lenses

A committee of the A.S.T.M. recommends that the term "lens" be used to refer to the combination of simple lenses which makes up the objective, by means of which a real image of the object is produced within the tube of the microscope, or the ocular, or eye piece, which enlarges the real image formed by the objective in the focal plane of the ocular. The lens system includes both objective and ocular.

In addition to the magnification or increase in size of the image with respect to the object produced by a lens, the resolving power or ability to make visible fine detail is of great importance. The magnification produced by an objective may be determined approximately by dividing 250 mm. (the normal reading distance) by the equi-

valent focal distance of the lens. The resolving power depends upon the numerical aperture (N. A.) which in turn depends upon the angle of aperture, α , and the refractive index, n , of the medium between the lens front and the object, e.g., cedar oil in oil immersion lens.

$$N. A. = n \sin \frac{\alpha}{2}$$

On account of the shape of a lens, light focused from near the edge of the lens is not brought through the same point as light passing through the central part of the same lens. This defect is termed spherical aberration. In a somewhat similar manner light of different wave length (color) does not all focus at the same point; this is chromatic aberration.

Achromatic objectives are constructed by a suitable combination of optical glasses of different indices of refraction so that correction for two colors, red and violet, is made, thus reducing chromatic aberration considerably. In apochromatic lenses this correction is carried very much further so that three colors are brought to the same focus.

Canadian Glass Industry in 1918

The mining, metallurgical and chemical branch of the Canadian Bureau of Statistics has just issued an account of the glass industry of the dominion in 1918. It may appear to be a late date to issue statistics for the year 1918, but it should be remembered that the Bureau of Statistics is a comparatively new department, that Canada has been at war, and that about 7 per cent of the whole population was mobilized for the actual fighting line, while a very large number of men were employed in the manufacture of munitions and supplies for the army. This made a big inroad on a total population of less than eight million, consequently many departments have suffered and have not yet gained pre-war efficiency.

During 1918 nine firms were engaged in the manufacture of glassware; of these six confined themselves to the manufacture of lamp and lantern chimneys, drinking glasses, bottles and other pressed and blown glassware; two to vials and chemical glassware, and only one to sheet glass. The total production of glassware was valued at \$6,578,602, of which ware to the value of \$35,367 was exported. On the other hand, Canada imported glassware to the value of \$5,430,873, showing that the country produced only 54.9 per cent of its actual requirements. The total capital invested in the industry was \$7,443,525, employment was given to 2,322 men and women, and \$2,221,563 was paid in wages. The raw material consumed was valued at \$2,056,739 and the fuel at \$598,886. Miscellaneous expenditures chargeable to manufacturing amounted to \$989,747, so that the total expenditures were \$5,882,295.

The following table gives the quantities and values of the raw materials consumed, all of which, with the exception of the soda ash, sodium nitrate and lead oxides, were of Canadian origin:

	Quantity	Value
Silica sand, tons.....	40,344	\$155,854
Soda ash, tons.....	13,468	635,068
Sodium nitrate, tons.....	95	7,905
Limestone, tons.....	4,490	18,076
Lime, tons.....	2,190	18,046
Carbon, tons.....	7	140
Arsenic, white, lb.....	68,314	8,694
Manganese dioxide, lb.....	18,535	1,414
Litharge and red lead, lb.....	169,986	17,764
Other chemicals.....		74,556
Miscellaneous, including crude glass and tubing.....		751,276
Boxes, cases, etc.....		367,946
Total.....		\$2,056,739

Selection of Fuel for Industrial Heating*

THE selection of fuels for industrial heating should be based upon appreciation of the radical difference between the price of fuel on the one hand and the quality and cost of product resulting from the generation, application and utilization of heat on the other.

The result sought from the application of heat is produced not by fuel or heat alone, but by a combination of equipment, fuel and operative. The nature of the heating process, the type and size of furnaces adapted to the manufacturing requirements, the plant conditions, the personnel, and price of available fuels or electrical energy are the controlling factors. Each of these must be considered, any one of which may influence the final choice.

COST PER B.T.U. DOES NOT TELL WHOLE STORY

The practice of selecting fuel on the basis of thermal value and price is both inaccurate and misleading unless at the same time proper consideration is given to other essentials which largely determine the suitability of fuel and equipment regardless of price or thermal value. Otherwise no other form of fuel could compete with bituminous coal burned in the open grate or blacksmith fire.

The form of equipment must be considered with reference to the manner of applying and utilizing the heat and of handling the material to be heat-treated, because these essentials are as directly linked to the quality and cost of finished product as are the price of fuel or method of generating heat, whether it be through combustion or the arc, induction or resistance methods of releasing heat from electrical energy.

Whenever there is a difference in physical or chemical form of fuel, or in mechanical form of equipment, there is a difference in economic value regardless of comparative thermal value.

It is as illogical to compare different forms of heat energy with regard to a certain result as it is to compare electricity with any one form of fuel on the basis of thermal value, unless proper consideration is given to the form of equipment adapted to each.

In industrial heating, as in illumination or transportation, much of the advantage frequently credited to some one form of energy is actually due to the appliance employed in connection with it. A different design of appliance or method of operating may reverse conclusions based on thermal value.

Frequently the "form value" of a suitable combination of equipment and fuel will prevail regardless of price. This is illustrated by the practice of using comparatively expensive gas for intermittent cooking operations in the kitchen in preference to comparatively cheap coal, which under different service requirements is preferable for heating the house. The advantages of incandescent electric lamps for the illumination of the interior of a railway coach may well be accompanied by the use of oil lamps as signals at the end of the train.

A FIELD FOR EACH FUEL

The nature of the heating process, manufacturing requirements and plant conditions may in many in-

stances make city gas at \$1 per thousand cubic feet economically preferable to oil at one cent per gallon or coal at \$1 per ton. In other instances, electricity at a very much higher price, based on energy cost, is given the preference because of the operating advantages made possible by a specific form of electric energy and appliance.

Frequently a fuel such as bituminous coal may be attractive on the basis of price but objectionable in form, or *vice versa*, as in the case of gas or electricity. Gases of the same physical form may vary greatly in chemical composition, which in itself may limit the field of usefulness regardless of price. Suitable furnace design may overcome these objections. Thus the use of bituminous coal is made possible in enameling furnaces by the use of a muffle, which might be unnecessary in electric furnaces in which gases, if any, originating from the resistance material did not affect the product to be heated.

The innumerable factors controlling the selection of fuel and the generation, application and utilization of heat for industrial or domestic purposes denote a field of usefulness, in suitable apparatus, for all varieties of solid, liquid, gaseous and electrical fuel or heat energy. Expansion in the use of any one form automatically follows the development of apparatus for converting that form of energy into useful service. The apparent relative economic value of the different forms on the basis of price at the moment may be changed in the future, as it has been in the past, by the development of better methods of heat application and more efficient apparatus to make possible either a different result or to accomplish the same result at less cost, by decreasing the amount of energy required without any change in the price.

COMPARATIVE FUEL PRICES ON B.T.U. BASIS

The chart gives a means for comparing fuels on the basis of their B.t.u. cost—by direct comparison of the price of one fuel with the price of another; by comparison of the relative costs per million B.t.u., or, on an assumed cost per million B.t.u., reading directly the "permissible" prices for various fuels.

The horizontal lines represent prices for fuels; the vertical lines, costs per million B.t.u. of heat energy; the diagonal lines are the plotted heat unit values of fuels. The chart is read by converting the price of a given fuel (horizontal line), at its intersection with the diagonal line of the heat unit value of the fuel in question, to the vertical intersecting line which, read at the bottom of the chart, indicates the cost per million B.t.u., or *vice versa*.

To illustrate: For a comparison of 12,000 B.t.u. coal at \$5 per ton with fuel oil. Reading from the left scale, the horizontal line from \$5 per ton is followed to its intersection with the diagonal value line for 12,000 B.t.u. coal, then vertically down to the scale at the bottom of the chart, which indicates a cost of approximately 21c. per million B.t.u. The same vertical line is followed to its intersection with the diagonal value line for fuel oil, then horizontally to the scale on the right of the chart, which indicates a price of approximately 3c. per gal., at which such fuel oil would have to be procured to equal on a heat unit cost basis 12,000 B.t.u. coal at \$5 per ton.

Reversing this process, if fuel oil should cost 8c. per gal., this horizontal line carried to its intersection with the fuel oil diagonal, then down to the bottom,

*Excerpts from a pamphlet, copyrighted 1921, by W. S. Rockwell Co.

indicates a cost of approximately 56c. per million B.t.u. This same vertical line carried to its intersection with the 12,000 B.t.u. coal diagonal, then horizontally to the left, indicates a comparative price for coal of \$13.50 per ton. Direct comparisons are thus available between the coal and fuel oil prices; indicating that fuel oil would have to be available at 3c. per gal. to equal in heat unit cost 12,000 B.t.u. coal at \$5 per ton; and that if fuel oil cost 8c. per gal., 12,000 B.t.u. coal would be no higher in B.t.u. cost at \$13.50 per ton.

This method of comparison takes into account the cost per million B.t.u. merely as an intermediate step. If desired, fuel prices may be compared directly. For example, following along the horizontal line of \$5 per ton coal to its intersection with the diagonal 12,000 B.t.u. coal value line, then vertically down to the intersecting diagonal line for fuel oil, then horizontally to the right, reading directly the comparative price of 3c. per gal. for fuel oil.

At an assumed cost per million B.t.u., the "permissible" prices for the various fuels to be considered will be found by following the vertical "cost per million B.t.u." line to its intersection with each of the fuels in question, then to the right or left respectively to read the "cents per gallon" for a liquid fuel, the "dollars per ton" for a solid fuel, or the "cents per thousand cubic feet" for a gaseous fuel.

HEATING VALUE OF GASEOUS FUEL

If mass generation of heat is considered without reference to its nature or use, then the B.t.u. cost of

fuel would be the factor determining the choice. In addition there must be considered the chemical composition of the gas and of the mixture of gas and air supplied for combustion, and also the influence of the design of furnace or other appliance employed for the generation, application and utilization of the heat.

The chemical composition of a gas fixes the volume of air required for combustion, and the mixture so formed, from which the heat is released, has a B.t.u. value per unit of volume much less than that of the original gas itself. The quantity of air required for combustion of the various gases fluctuates greatly, being more for the richer gases and in general less with the decrease in B.t.u. value.

The heat unit value of the usual industrial gases may vary from 100 to 1,500 B.t.u. per cu.ft.; the theoretical quantity of air required for combustion may vary from 1 to 12 cu.ft. per cu.ft. of gas; the B.t.u. value of the combustible mixtures of these same gases, with the theoretical quantity of air required for combustion, may vary from 50 to 115 B.t.u. per cu.ft., or less with an increase in the relative quantity of air supplied. See Table I.

The B.t.u. value of a gas or its combustible mixture does not indicate the temperature obtainable by combustion or determine its field of usefulness.

Natural gas at 900 B.t.u., while apparently three times as rich as water gas at 300 B.t.u. per cu.ft., has a lower flame temperature and rate of flame propagation. Natural gas would not be as suitable as water gas for high-temperature blow-pipe operations such as

TABLE I. CHARACTERISTICS OF VARIOUS INDUSTRIAL GASES

	Acetylene	Natural Gas	Coal or City Gas	Coke-Oven Gas	Carburetted Water Gas	Oil Producer Gas*	Fuel Gas†	Water Gas	Producer Gas	Blast Furnace Gas

* Oil gas made with air in internally fired retort or generator. † Gasification by continuous process, using hot coke for water gas, and blow-up gas to heat retorts.

welding. On the other hand, natural gas is preferable in internal combustion engines, in which the air and gas are mixed under heavy compression.

Producer gas, in its washed state, while suitable for gas engines, is not as well suited as water gas for high-temperature operations, such as forging or welding, yet with regenerative furnaces it is extensively used for melting steel. The design and operation of the furnace favor a field of usefulness which is not disclosed by an analysis of the gas itself. Both the gas and the air required for its combustion may be preheated to a high temperature in such regenerative furnaces, whereas if natural gas were employed in the same furnaces the preheating would be limited to the air alone, because the natural gas, by reason of its chemical composition, would dissociate in the regenerative chambers at such high temperatures.

The distribution of natural gas is frequently affected in cold weather by the formation of solids in the pipe lines. The distribution of carburetted water gas under similar conditions frequently results in the deposition of oil in the pipe lines resulting from condensaton of certain hydrocarbons peculiar to this gas. Producer gas, while relatively cheap and less susceptible to such conditions in transportation, is not suitable for general distribution by reason of its low heating value and unusually high percentage of incombustibles.

Many examples from everyday practice with various forms of fuel could be given to illustrate the point not generally appreciated, that the difference in composition or "chemical form value" of industrial gases, the influence of the quantity of air supplied for combustion, and the design of the appliance, denote fields of usefulness and limitations which are not revealed by the customary B.t.u. comparison.

IMPORTANCE OF COMPOSITION

The fundamental significance of chemical composition as affecting the quality and cost of product must be considered in the selection of gases and of equipment for the transformation and application of their energy values.

When the material difference in B.t.u. value of the common industrial gases is considered together with the comparatively slight difference in heating value of their combustible mixtures, it is apparent that chemical composition is of greater importance than B.t.u. value in determining their field of usefulness.

The quantity of inerts or incombustibles is relatively small in the majority of industrial gases, with the exception of producer gas. The inert content is important in so far as it relates to the increase in volume of gas or combustible mixture necessary to furnish a given amount of heat energy, and to the

nature and cost of equipment and operations necessary for manufacture and distribution; but it is apparent from comparison of the inert content of the combustible mixtures of the different gases that the heating value of the gases is determined more by the elements forming the combustibles than by the percentage of inerts in the gases or in their combustible mixtures.

Consideration of the comparatively large volume of products of combustion of each gas, which are heated to the maximum temperature of the heating process, will indicate the economies attainable through efficient utilization of the spent gases to perform useful work. The heat in these gases may be utilized to preheat the air or fuel prior to combustion, or, as is generally more desirable, to preheat the material before it is exposed to the final working temperature.

The composition of the products of combustion must be considered in relation to its influence upon the product, because furnace atmosphere plays an important part in some processes which may require either reducing, neutral or oxidizing conditions. Frequently the apparent advantages of a comparatively cheap fuel may be offset by the chemical action of the resultant gases upon the process or apparatus, which would necessitate modifications in the furnace design or process in order to retain the advantage that may be represented by the form or price of such fuel. This is illustrated by the practices of employing crucibles for melting certain metals to decrease the possible effect of oxidation; of packing material in sealed boxes or pots; and by the muffle type of furnace employed for vitreous enameling; in each case permitting the application of heat without contact between the material to be heated and the products of combustion. Special atmospheres may be secured in muffles by passing suitable gases into the muffle, which may or may not be sealed.

Such limitation is not confined to fuels alone, as it is frequently encountered in the arc of resistance methods of releasing heat from electricity due to the gasification of the electrodes or resistance material. In most cases it is desirable to maintain neutral or reducing atmosphere in the heating zone to protect the material from oxidation. While this may be readily accomplished with most fuels in properly designed furnaces by control of the air supplied for combustion, it is comparatively difficult with others. Such a neutral or reducing atmosphere may be readily secured in electric furnaces releasing heat through some form of carbonaceous resistance material, while a different form of resistance material may necessitate the use of a material such as oil to provide the proper atmosphere in the heating zone, even though the heat itself is generated by an electrical process.

Electrically Heated Glass-Annealing Lehrs

BY E. F. COLLINS*

THE accurate degree of temperature control through a cycle of temperatures which is necessary in annealing glass and the difficulty of securing it in the ordinary fuel-fired lehr have led to experiments with a view to developing electrically heated lehrs. One such lehr which has been running several months on a high grade of glass ware and on which reliable overall factory costs have been kept shows a decrease in cost per unit annealed of 20 per cent. This saving is about seventy-five times the total cost of power for heating the lehr.

Generally speaking, the annealing temperature for glass is that constant and uniform temperature at which any stresses which exist in the ware are permitted to relax. The length of the anneal, of "annealing time," depends on the magnitude of the stresses existing before annealing occurs, being a function of each point within the necessary temperature range.

In all glass annealing it is of vital importance that the temperature of the glass mass should be very uniform in the annealing range. Temperature gradients in the mass of homogeneous glass under treatment are solely responsible for setting up strains. These gradients may result either from too rapid cooling, or from a non-uniform and uneven heat distribution. Hence the importance of heat control with respect to time and also proper heat distribution in the lehr through which the ware is passing.

Where glass is treated in the box type oven it is also extremely important that the distribution be good and that the heating equipment lend itself to the exact following of the time-temperature cycle desired, whether it covers a few hours—or a month. Preferably this control should be automatic and correspond to a predetermined cycle. It is for this reason that electrically heated lehrs are successful.

Such automatic control with limits of plus or minus 2.5 deg. C. is available if electrically heated lehrs of proper design are used.

An example of temperature distribution in an electric furnace is given in Fig. 1, with its accompanying table.

*General Electric Co.

FIG. 1. TEST DATA OF HEAT UNIFORMITY OF ELECTRIC FURNACE

Time	Thermocouples—Temp. °C.					Average Temperature	Per Cent Deviation From Average	Rate of Change, Deg. per Hr.
	1	2	3	4	5			
11.30	25	25	25	25	25	25	0	0
3.30	527	537	532	530	545	534	2.07	1.31
7.30	670	679	671	666	669	669	1.05	0.45
11.30	777	783	776	766	780	776	1.00	1.03
3.30	858	864	857	849	864	860	0.46	1.03
7.30	860	865	862	862	863	862	0.35	0.23
11.30	928	934	930	930	928	930	0.43	0.21
3.30	933	932	927	925	927	929	0.64	0.43
4.30	950	950	952	952	955	952	0.31	0.21

It will be noted on this record of temperature distribution that for a rising temperature of 125 deg. C. per hour over the first four hours only one point varies from the mean temperature by 2.07 per cent. Over the next four hours, with 35 deg. C. change per hour, the maximum variation from mean temperature is 1.5 per cent. The maximum at the rate of 17 deg. C. per hour is 0.43 per cent, while at constant temperatures, at 860 deg. C. the variation is 0.35 per cent, and at 930 deg. C. 0.64 per cent. These figures are for an oven 6 ft. 6 in. in diameter, and 7 ft. 6 in. deep. Such accuracy of control and evenness of heat distribution as these figures show would seem to meet the most exacting requirements of any and all types of glass annealing, including that of large lenses for telescopic work.

Fig. 2 is a graphic representation of the time temperature cycle for annealing fine crown glass for a telescope lens. Such process is best carried on in the

FIG. 2. TIME-TEMPERATURE CYCLE FOR ANNEALING CROWN GLASS LENS FOR TELESCOPE. BOX TYPE ANNEALING OVEN

box type of lehr in which the lens is placed and subjected to a temperature cycle as shown. With electric heat, automatic control is available by means of which this particular cycle or any similar one may be accurately followed and repeated exactly whenever desired. The control instrument is operated by a time-keeping motor supplemented by a simple cam arranged to give different rates of heating or cooling, according to the predetermined characteristic as shown on the curve.

Exact operating costs for electrically heated lehrs are not yet available, but from estimates made for such work it is believed that costs will be greatly in favor of the electrically heated lehr, especially when the improved quality of the product, increased production and elimination of rejects are taken into account.

The factors that assist in turning out better products are, first, there is no opportunity for the ware to absorb the products of combustion, hence no sulphuring takes place, and the product has a bright, polished surface requiring no washing or cleansing. Second, the ware is sterile and absolutely clean, due to the heat, which is important for prescription ware, allowing medicinals to be sealed in as soon as the ware leaves the oven. Lastly, there is the low-temperature gradient, which eliminates breakage, distortion and products developing flaws under the tests given after annealing.

Philippine Sugar Exports

During the period from March 1 to April 15, this year, the Philippines exported 16,189,944 kilos of sugar worth \$2,044,018. Of this quantity 7,941,470 kilos was centrifugal valued at \$1,019,379. The rest was raw sugar amounting to 8,246,674 kilos, worth \$994,599. More than 6,000,000 kilos of the centrifugal sugar exported, worth approximately \$1,000,000, was sent directly from Manila to the United States.

Synopsis of Recent Chemical & Metallurgical Literature

Allotropic Varieties of Oxides.—A study of the conductivities of a certain number of metallic oxides such as CeO_2 , Cr_2O_3 , NiO , CuO , TiO_2 , Mn_2O_3 , MnO , SnO_2 , SnO , Fe_2O_3 , Fe_3O_4 , ZnO and CdO shows that these oxides act like electrolytes and carbon. Their conductivity is a function of temperature, the representative curve being parabolic. Some oxides show peculiarities which can be attributed to allotropic varieties of these oxides.

Miss S. Veil has made a study of the allotropic varieties of such oxides, with special reference to magnetic iron oxide and cadmium oxide, and presented the results of her work at the May 6, 1921, meeting of the French Academy of Sciences. (*Comptes rendus*, vol. 172, pp. 1405-1407.)

FIG. 1. REGION OF CURIE POINT FOR MAGNETIC IRON OXIDE

In studying magnetic iron oxide Miss Veil found that the conductivity-temperature curve presents a change of direction between 500 and 600 deg. C. (Fig. 1) and that this change corresponds to the Curie point, temperature at which the natural magnetite loses its magnetism. She has worked with temperatures varying up to 1,300 deg. C., but no other change of direction occurs after the Curie point. In cooling, the Curie point is not visible, and this indicates that the system does not pass through an analogous series of states when heated and when cooled. For the same temperature the conductivity is greater during cooling than during heating, as can be seen by the plotted curves.

The Curie point as fixed by Curie is 535 deg. C., whereas

FIG. 2. CHANGE OF CONDUCTIVITY OF CADMIUM OXIDE WITH INCREASE IN TEMPERATURE

Weiss gives it as 580 deg. C. The first was determined by measuring the magnetic susceptibility, the second by the combination of magnetic and specific heat measurements. The Curie point as shown in the curve does not correspond exactly to either of these figures, this being due to hysteresis phenomena and to inherent irregularities in conductivity of oxide briquets.

Cadmium oxide has already an appreciable conductivity at ordinary temperatures (Fig. 2). An increase in temperature increases normally the conductivity, following a parabolic curve, up to about 200 deg. C., when the curve decreases up to about 550 deg. C., then increases again up to the second maximum, at about 850 deg. C., and finally decreases until at 1,300 deg. C. it reaches a conductivity which is only a small fraction of that at normal temperature.

These results can be interpreted by admitting that cadmium oxide presents three allotropic varieties of cadmium oxide—namely, α , β , and γ , whose stable regions are located on both sides of the maxima. Thus the region of the variety α is approximately between the ordinary temperature and 200 deg. C., that of the variety β between 200 and 850 deg. C., and finally that of γ at temperatures above 850 deg. C. The conductivity of the α and β varieties is about of the same order, whereas that of the γ variety is relatively very small.

In cooling rapidly, beginning at 1,300 deg. C., the conductivity remains very small, because the velocity of transformations is too small to take effect during rapid cooling, but if the cooling to normal temperature is slow and is realized only after many weeks, the oxide regains the variety α and shows the corresponding conductivity.

New Developments in the Manufacture of Tungsten and Its Compounds.—Moissan succeeded in melting tungsten in his electric furnace, but in extremely small quantities only and at the expenditure of considerable energy. Hugo Lohmann reports in *Electrochemisches Zeitung*, vol. 26, pp. 29-33, that he has been able to make comparatively large quantities of the crude metal and to obtain therefrom a thoroughly fused carbide in a specially designed furnace. The latter was of the arc type, but was constructed in such a manner that the principal disadvantages of this kind of furnace—viz., the smallness of the source of heat and the space within which it can prevail—are eliminated. It was possible to melt 5 kg., or 12 lb., of amorphous tungsten within fifteen minutes in this furnace. The current consumption is very low. Besides the carbide of tungsten, carbides of titanium, vanadium, zirconium, silicon, boron and uranium were obtained as well.

The hardness of tungstic carbide is 9.8 on Moh's scale. This substance was produced in large quantities and was used with great success to replace the industrial diamond, bort, in all its applications. By melting the carbide it was found that it could be produced in a strong, compact state so that it could be employed in making dies for wire-drawing machines, in fabricating cutting tools of all sorts, boring apparatus, etc. There appear to be important economic as well as technical advantages in favor of the carbide.

The melting of tungsten and the making of castings, forgings, etc., with the metal have rendered it usable for many purposes for which it could not be used hitherto. It was found that high-speed cutting tools made from tungsten gave very remarkable results in their durability and the thickness of the cut. Any tool or machine part that must stand up against extreme wear and exceedingly high temperatures caused by frictional resistance or otherwise has been improved very greatly by being made from the pure fused tungsten metal.

The author has prepared molten uranium at a temperature of 3,500 deg. C. in large quantities. He has used the metal in making the target in X-ray tubes and found that the results corroborated the theory that the higher the molecular weight of the target metal the more effective the X-ray apparatus. He also used the metal in making the contact points for the spark-plugs of gas engines, and instead of platinum for the contact wire in incandescent lights.

Current Events

in the Chemical and Metallurgical Industries

Investigation of the Dye Industry

Opponents of the special dye legislation have recently introduced resolutions in both branches of Congress calling for investigations of the dye industry. Some time ago Senator King of Utah presented a resolution requesting the appointment of a special committee to investigate the existence of a dye monopoly and its employment of lobbyists for the purpose of influencing tariff and other legislation. After this was referred to the Senate Committee on the Judiciary, that committee on July 12 reported a resolution similar in substance and intent, although the investigation was to be carried out by the Committee on the Judiciary or a sub-committee of it.

Congressman Frear, following his recent denunciation of the dye section of the Fordney tariff bill and his attack on the officials of the Chemical Foundation, introduced a resolution in the House requesting the Attorney General to instigate legal proceedings against the Chemical Foundation for its alleged fraudulent purchase, control and license of the patents obtained from the Alien Property Custodian.

Eugene Schneider Receives John Fritz Medal for 1922

With the presentation of the John Fritz Medal to Eugene Schneider, head of the famous Creusot Works, in Paris on Friday, July 8, by a mission of American engineers, came cable advices from London to the national headquarters of the American Society of Mechanical Engineers in this city announcing that more foreign honors had been conferred upon Americans distinguished in the engineering profession.

The cable message, addressed to Secretary Calvin W. Rice, stated that Ambrose Swasey of Cleveland, sponsor of the Engineering Foundation and past president of the American Society of Mechanical Engineers, has been elected to honorary membership in the British Institution of Mechanical Engineers, in the British Institution of Mining and Metallurgy and in the Institution of Mining Engineers.

Charles F. Rand of New York, it was stated, has been elected an honorary member of the Institution of Mining and Metallurgy and of the Institution of Mining Engineers. Mr. Rand, who is chairman of the executive board of the Engineering Foundation, has just been made an honorary member of the British Iron and Steel Institute.

Other elections announced by cable were those of Colonel Arthur S. Dwight of New York and William Kelly of Vulcan, Mich., to honorary membership in the Institution of Mining Engineers. This group of honors is believed to be without precedent in engineering and was described by Mr. Rice, who has been active in promoting closer relations between American and British engineers, as an important step in bringing about world solidarity in the engineering profession. A movement, it was said, has been started in the direction of federating the engineering societies of the British Empire according to the general plan adopted by Herbert Hoover and his associates in organizing the Federated American Engineering Societies, in which are gradually coalescing the national and local engineering organizations of the United States.

The ceremonies in Paris, participated in by a special deputation of thirteen American engineers under the general chairmanship of Mr. Swasey, followed similar ceremonies in London on June 29, when the John Fritz Medal for distinction in applied science was presented to Sir Robert Hadfield, known for his work in the development of manganese steel. The Hadfield award was for 1921 and the Schneider award for 1922. M. Schneider received the gold medal in person for his achievements during the war "in

the industrial and scientific defense of civilization."

The John Fritz Medal Board of Award, in conferring the honor, lauded M. Schneider's "achievement in the metallurgy of iron and steel, in the development of ordnance, especially the 75-mm. gun, and in notable patriotic contribution to the winning of the war."

Mr. Rand, it is said, becomes one of five honorary members of the Iron and Steel Institute, the others being the Prince of Wales, King Albert of Belgium and Dr. Richard Akerman and Baron Gustaf Tamm of Stockholm.

Chemical Exposition Plans

Plans to make the Seventh Annual Exposition of Chemical Industries the greatest in the history of the industry are progressing favorably. Being held during the week of Sept. 12, it will follow immediately the meeting of the American Chemical Society and the Society of Chemical Industry, and the sponsors of the display report more interest than ever, not only in the chemical industry itself but in the wide range of related industries.

Thus far more than 400 exhibitors will have places in the exposition, and before the books are closed Fred W. Payne, who, with Charles F. Roth, is managing the exposition, expects that last year's total of 457 will be exceeded. It is certain that every branch of chemistry will be represented and that the public will be introduced to many new and important phases of chemical development.

The 1921 display will present to the visitor a somewhat different aspect from its six predecessors. The Eighth Coast Artillery Armory can take care of all the exhibits on its one vast floor, comprising 180,000 sq.ft. Thus the appearance of the show will be much more impressive than it was staged on four floors of Grand Central Palace.

Technical sessions will be held in the auditorium, which is a solid brick, fireproof structure at one end of the building. Plans for these meetings include symposia on chemical engineering subjects: one on evaporating and drying, another on crushing, grinding and pulverizing and a third on material handling equipment. The following programs are only preliminary and details will be given in subsequent issues.

Papers on crushing, grinding and pulverizing include: "Ball and Pebble Milling for Pulverizing and Mixing," by H. F. Steinfeldt, of the Abbe Engineering Co.; "Grinding and Pulverizing With Air Separation," by S. B. Kanowitz, of Raymond Bros. Impact Pulverizer Co.

The following speakers are announced for the evaporating and drying symposium: E. G. Rippel, Buffalo Foundry & Machine Co.; A. E. Stacey, Jr., Carrier Engineering Corporation, "The Relation of Atmospheric Conditions to Chemical Processes"; H. S. Landell, Proctor & Schwartz, "Drying and Drying Problems"; Max Donauer, Elyria Enameled Products Co.; Arthur B. Stonex, Hunter Dry Kiln Co., "Drying With Moist Air"; A. S. Lissauer, W. L. Fleisher & Co., "Drying as an Air-Conditioning Problem"; J. D. Stein, Grinnell Co., Drier Division, "Atmospheric Drying by Means of Compartment, Tunnel and Continuous Belt Conveyor Driers With Some Practical Applications"; M. H. Dickerson, Atomized Products Co., "Spray Drying."

Motion pictures will also be shown in the auditorium. Films covering nearly every phase of the chemical industries have been promised. The following are representative: "Saving Wasted Millions Through Material-Handling Equipment," two reels (Courtesy of Economy Engineering Co.); "Conserving Coal and Saving Heat Values by Insulating Steam Pipe and Boilers," one reel (Courtesy Magnesia Association of America); "The Manufacture of Pyrex Glassware," three reels (Courtesy of Corning Glass Co.); "The Story of Sulphur," two reels (Courtesy of Texas Gulf Sulphur Co.)

American Electroplaters' Society Convention

Under the present industrial conditions it was very encouraging to find about 150 foremen electroplaters at the annual convention of the American Electroplaters' Society at Indianapolis, June 29 to July 2. The attendance was somewhat below normal, due in part at least to the failure of employers to pay the expense of their electroplaters, as many have done in former years. In times of industrial depression it is more important than ever to utilize opportunities for research and development, such as are to be gained from educational conventions; and manufacturers may well pay as an investment at least part of the expenses of their employees to such gatherings.

The large number of technical papers presented and the interesting discussions that ensued demonstrated that this organization is rapidly becoming a truly technical society and that through its efforts great progress has been and will be made in the electroplating industry. Several chemists interested in electroplating were present. The number should be increased to mutual advantage, as the chemists can often aid in the explanation of technical points and can at the same time become better acquainted with the platers and their point of view and thereby co-operate more effectively with them.

ELECTRO-ANALYSIS OF PLATING SOLUTIONS

It is significant that a number of the papers presented dealt with research problems and methods. Dr. Hiram S. Lukens, of the University of Pennsylvania, explained in detail various "Electrolytic Methods for the Determination of the Metal Content of Plating Solutions." Electro-analysis is an especially simple and appropriate method for persons engaged in electrodeposition. Emphasis was laid upon the fact that entirely satisfactory results may be obtained by the use of cathodes of copper or nickel, thus eliminating the expense for platinum. The various possible reactions occurring during electrodeposition and the advantage of control by chemical analysis were very clearly explained. The society, and especially the Philadelphia branch, are to be congratulated for securing the assistance and co-operation of Dr. Lukens, and the use for branch meetings of the laboratory at the University of Pennsylvania. Other educational institutions may well follow this example, as has been done by the University of Cincinnati and a few others.

ADDITION AGENTS IN ELECTRODEPOSITION

Dr. F. G. Mathers, of the University of Indiana, gave an interesting address upon the use of "Addition Agents in Electrodeposition, and showed a large number of specimens of lead, tin, antimony and silver deposited in the presence of specific addition agents. Dr. Mathers' paper emphasized the great possibilities in this field and especially the need for further research to explain the causes for the observed effects. Until such further knowledge is obtained, the general application of addition agents in electroplating will be rather limited. This field deserves extended investigation.

STRUCTURE OF BASE METAL AND ELECTRODEPOSIT

George B. Hogaboom, of the Scovill Manufacturing Company (and electroplating adviser to the Bureau of Standards), touched upon an almost entirely new subject when he explained the "Relation Between the Structure of the Base Metal and That of the Electrodeposit." He exhibited numerous photographs which showed clearly that some of the defects and difficulties encountered in electroplating are due not to improper composition of the solution or conditions of operation, but to defective structure of the brass, steel or cast iron upon which the metal was deposited. This subject is of far-reaching importance, as it emphasizes the fact that for successful electroplating the knowledge and services of the metallographist may be as important as those of the chemist and the plater. It is an all too common mistake to assume that electroplating can be used to cover or hide defective material or workmanship!

Several papers were presented upon nickel plating, among which may be mentioned those by R. Suman, of the National

Cash Register Co., and William Blum, of the Bureau of Standards, upon the use of fluorides. The latter paper summarized the work recently presented to the Electrochemical Society and also published in *CHEMICAL & METALLURGICAL ENGINEERING* (vol. 24, pp. 1109-1115, June 22, 1921). From the discussion that followed it appears that nickel solutions containing hydrofluoric or fluorides have been successfully used in several plants during the past year.

W. Blum and T. F. Slattery described the process for the electrolytic reproduction of engraved printing plates, recently installed at the Bureau of Engraving and Printing under the direction of the Bureau of Standards. In this process the printing surface consists of a heavy deposit of nickel (produced in solutions containing fluorides). The body of the plate, which is about 0.25 in. thick, consists of alternate layers of copper (each 0.003 in.) and nickel (each 0.001 in.). The use of such layers, first suggested and patented by George U. Rose, Jr., is advantageous in producing a stronger plate and in decreasing the treeing and thus permitting the use of higher current densities. Details of the process will be published in the near future.

W. Blum and M. R. Thompson, of the Bureau of Standards, presented a paper on the "Acidity of Nickel Plating Solutions," illustrated by experiments and charts. The meaning, measurement and expression of hydrogen ion in concentration were explained in simple terms, and the distinction between the degree of acidity and the amount of acid was emphasized. The use of indicators for the approximate measurement of the p_H of solutions was illustrated. The function of boric acid and of fluorides was shown to be in part that of "buffers"—i.e. regulators of acidity. Specimens of nickel deposited at definite p_H were exhibited.

In a paper by O. W. Storey, of the Burgess Laboratories, the use of methyl red for the factory control of the acidity of nickel solutions was described. This method, used by the author for the past eighteen months, illustrated admirably the practical applications of the principles described in the preceding paper.

COST ACCOUNTING

W. J. Allen, of Grand Rapids, in a paper upon "Cost Keeping in Electroplating" showed that it is entirely possible to determine approximate or average costs both in factory plating and in job plating. This subject is of special interest to engineers and manufacturers, as electroplating is often considered simply as a "necessary evil" and little thought is given to the relation between cost and quality or to the possibilities of real economies in operation.

PLANS FOR RESEARCH

A report was rendered upon the work and plans of the Bureau of Standards in the field of electrodeposition. The effort now being made by the National Research Council to obtain from interested manufacturers funds to augment research in electroplating was explained, and electroplaters were urged to assist in getting such support. All the papers upon the program emphasized the needs and possibilities for investigation in this fertile and important field, and manufacturers will no doubt take advantage of this opportunity for co-operative research.

The social features of the convention were very successful, and in spite of the hot weather all those present felt well repaid. The business sessions and elections were harmonious and showed the true spirit of co-operation. Few if any technical societies can point to as much real progress in less than ten years of existence as the American Electroplaters' Society.

Object to Tea Waste Duty

Objections are reaching Washington to the provision of the Fordney tariff bill which makes impure tea, tea waste, tea siftings or sweepings dutiable at 1c. per lb. The contention is that this important source of caffeine should be admitted free of duty.

While the Fordney bill advances the duty on caffeine itself from \$1 to \$1.50 per lb., it leaves unchanged the provision of the Underwood act which levies 1c. per lb. on the raw material from which caffeine is made.

Bureau of Mines Petroleum Experiment Station Seeks Technical Men

The Petroleum Experiment Station of the United States Bureau of Mines at Bartlesville, Okla., plans to enlarge its program of work and to employ a few additional technical men for conducting the different investigations. Funds for this work are provided by the State of Oklahoma, and for that reason it will not be necessary for applicants for the new positions to take civil service examinations. Persons interested should write H. H. Hill, superintendent Petroleum Experiment Station, Bartlesville, Okla., furnishing a statement of their education, experience and positions held and salary, together with a photograph taken within the past year.

The following is an outline of the positions open and the qualifications for each:

Petroleum Engineer for Work on Water Problems: Applicants for this position should be graduates from a college or university, with a degree in geology, or in mining, mechanical or civil engineering. The applicant should have had at least five years' oil-field experience, of which at least three years should have been on work connected with the development and production of petroleum. The applicant also should have had considerable experience in the solution and correction of water problems in producing oil and gas wells. Salary range \$3,000 to \$3,600 per annum.

Expert Driller: Applicants for this position should have had at least five years' actual drilling experience with cable tools; also experience in shutting off water by the use of mud-laden fluid and cement. Preference will be given to a man who has had supervisory work in connection with mudding, cementing and plugging of wells. Preference will also be given to a man who has had rotary drilling experience. Salary range \$3,000 to \$3,600 per annum.

Natural Gas Engineer: Applicants for this position should be graduates from a university or college with a degree in engineering, preferably mechanical engineering. At least five years' experience in work connected with the transmission of natural gas is required. This experience should include a knowledge of methods of metering natural gas, compressor stations and field equipment. Preference will be given to a man who is familiar with field conditions and who has had experience in the determination of pipe line losses. Salary range \$3,000 to \$3,600 per annum.

Assistant Petroleum Engineer: Applicants should be graduates of a college or university with a degree in geology or engineering. Applicants must have had at least one year's field experience in engineering work as applied to underground problems in oil fields. Salary range \$1,800 to \$2,400 per annum.

Co-operative Factory Investigation on Fish Scaling of Enamels

The committee on research and development of the Enamel Division of the American Ceramic Society is conducting a co-operative factory investigation of fish scaling based on the results of the Bureau of Standards research in this subject. The committee met at Cleveland, Ohio, on June 20, when a comprehensive study of this work on a factory scale was outlined. Steel and iron sheets will be prepared by the mills represented on the committee, and these will be manufactured into enameled ware in the enameling factories co-operating in the work. Some work will also be done by the enamelers in checking results obtained with enamel compositions and in annealing of enameled ware as developed at the bureau.

The preliminary report on the laboratory results as obtained by the bureau will be published in an early number of the *Journal* of the American Ceramic Society. The results of the co-operative work when completed will be combined with the laboratory results and issued later as a technologic paper.

The following members of the Enamel Division are serving on the committee:

R. R. Danielson, chairman, Bureau of Standards, Washington, D. C.; H. C. Arnold, A. D. Little Laboratory, Cambridge, Mass.; J. F. Bardush, Grand Rapids Refrigerator

Co., Grand Rapids, Mich.; J. S. Grainer, Challenge Refrigerator Co., Grand Haven, Mich.; D. M. Buck, American Sheet & Tin Plate Co., Pittsburgh, Pa.; J. A. Aupperle, American Rolling Mill Co., Middletown, Ohio; R. D. Cooke, Columbia Enameling & Stamping Co., Terre Haute, Ind.; J. B. Tyler, Lisk Mfg. Co., Canandaigua, N. Y.; E. P. Poste, ex-officio, Elyria Enameled Products Co., Elyria, Ohio.

Exchange of Wood Waste Through the Forest Products Laboratory

The Wood Waste Exchange of the U. S. Forest Service has been transferred from Washington to the Forest Products Laboratory, Madison, Wis., where its future activities will be centered. The Exchange has in the past contributed much toward more complete utilization of wood, by supplying a medium through which the mills and wood-using factories could locate markets for their side lumber and short lengths, and wood-consuming factories sources of material which would meet their requirements.

Centering the activities of the Exchange at the Forest Products Laboratory will permit an expansion of this service, in that it will be possible to include suggestions as to markets and new uses for byproducts and low-grade material, based on the latest results of technical research carried on by the laboratory. As both the Forest Products Laboratory and the Association of Wood Using Industries have pointed out, there is a large wastage of wood annually because of ignorance on the part of manufacturers of one another's wood requirements.

Quarterly reports on "Opportunities to Sell Waste," similar to those issued in the past, will be sent to all concerns which wish to be listed as having wood byproducts and waste in any form for sale. These reports will contain the names and addresses of manufacturers of various wooden products who could under suitable conditions use raw material from these sources, together with information as to kinds, sizes, form and condition of the stock desired. Suggestions as to the proper methods of caring for the material until it is ready for market will also be included.

A similar report on "Opportunities to Buy Wood Waste" will be sent to wood-using factories and other consumers who ask to be listed for this service. This report will contain information relating to manufacturers who have such material and its character, quality and amount available.

None other than actual producers or consumers of wood stock of this character can become patrons of this Exchange. All communications should be addressed to the Director, Forest Products Laboratory, Madison, Wis.

National Lime Association Urges Protection for Dye Industry

Although the lime industry is not directly interested in the dye industry, a careful analysis of the situation has convinced the members of the National Lime Association that the best interests of the country and those of the chemical and allied industries in particular demand the passage of protective legislation. Accordingly the following resolution was passed unanimously at the recent convention of the association and a copy was sent to each member of Congress.

Whereas a complete, self-sustained coal-tar chemical industry is essential to the industrial development of our country, to its national safety and security, and is important in its very close relation to medical science, and

Whereas it has been shown that unusual protection must be given by the Government to this industry, the development of which began only when the war gave it its opportunity, and that a tariff alone will not protect it adequately against the determined assaults of the German-government-fostered-chemical-cartel which is seeking to regain this, the world's richest market, now the only market without permanent protection; therefore, be it

Resolved, That the National Lime Association hereby urges upon Congress in solemn earnestness the prompt enactment of adequate legislation to protect and maintain in this country this vital chemical industry.

Ford Offers to Lease Wilson Dam and Buy Nitrate Plant

Henry Ford's offer to lease the Wilson Dam and to purchase the nitrate plant at Muscle Shoals promises to be disconcerting to some of the ultra-conservationists in Congress. They opposed Government development of the project both in bringing about the defeat of legislation looking to the formation of the United States Fixed Nitrogen Corporation and in refusing to appropriate for the continuance of the work on the Wilson Dam.

They are embarrassed greatly by Mr. Ford's offer. They fear that private enterprise will obtain the great bulk of the profits likely to come from the development of this resource. In defeating the proposals for Government operation of the Muscle Shoals projects Congress maneuvered itself into a position where it seems that it cannot refuse consistently to entertain a bona fide offer from a private interest. In doing so some of the conservationists fear the loss to the general public of the full advantages of one of their heritages.

Mr. Ford's offer is to lease for 100 years the completed Wilson Dam. On the total cost, Mr. Ford proposes to pay interest at the rate of 6 per cent. It is estimated that about \$28,000,000 will be required to complete the dam. He offers \$5,000,000 for the nitrate plant (No. 2), the steam plant, lands and other equipment.

Colonel Gilchrist Honored

A distinguished service medal has been awarded to Lieutenant Colonel Harry L. Gilchrist of the Chemical Warfare Service. The citation reads as follows:

Lieutenant Colonel Harry L. Gilchrist, Medical Corps, then Colonel, Medical Corps, for exceptionally meritorious and distinguished service as Chief of the De-lousing and Bathing Services of the American Expeditionary Forces. By his superior administration and splendid efficiency he contributed materially to the success achieved by the Army at the ports of Brest, Bordeaux and St. Nazaire, in the return to the United States of the American Expeditionary Forces.

Potash Duty Faces Hard Fight

It is very evident that great difficulty will be experienced in retaining the potash item in the tariff bill. Allegations that this duty will cost the farmers \$6,000,000 or more will be accepted by many members of Congress who represent large agricultural constituencies. Unusual interest is being taken in the matter by the representatives of the farmers, since most farmers have allowed their lands to become under-fertilized and have reached the point where they must make much larger purchases next year. To have anything interfere with possible decline in price brings forth loud complaint.

On the other hand, the representatives of the domestic potash producers point out that the duty in the form prescribed by the committee is not as satisfactory as a straight 50c. duty for which they contended. The duty as provided in the bill may take care of the plants in existence, but it certainly will not encourage any new capital to enter the industry. It also is pointed out that most of the schedules are much higher than they seem, since they are affected by the American valuations. This is not true in the case of any but chemical potash.

New Proving Ground Ready

Field tests of gases now can be carried forward rapidly by the Chemical Warfare Service. This is made possible by the making ready of the new proving ground adjacent to Edgewood Arsenal. This phase of the work of the Service has been interfered with greatly due to the fact that the proper equipment could not be installed at the Lakehurst proving ground when it was known that it was to be abandoned in the near future.

Since there is no uncertainty as to the tenure of the new proving ground, permanent facilities have been installed. These include machine shops, laboratories, field sampling outfits and the general equipment of an efficient proving

ground. In addition there is a light gage railroad which will make for great economy in the conduct of tests. There is the greatest need at the present time to be able to ascertain quickly and with exactness the concentrations of gas under conditions of actual use. General Fries believes that with the improved facilities of the new proving ground great headway will be made in that work. He admits, however, that there is great chance for improvement in the methods of ascertaining gas concentrations in the field. This problem is to be attacked vigorously by the technical men of the Service and it is hoped that valuable suggestions may be contributed by outside chemists.

Growth in French Porcelain Industry

At a recent meeting of the Syndicat des Fabricants de Produits Ceramiques de France, Paris, France, M. Guerineau, honorary president of the association, said that there has been a remarkable growth in the production of refractory materials in that country since the war. The output at the present time approximates 700,000 tons, which is said to be sufficient for all home needs; in 1914 the aggregate production was only 500,000 tons per annum. With regard to floor tile, M. Guerineau says that French producers are now in position to meet the entire home demand, which is quite considerable, including pavement and floor tiles, whether semi-opaque or incrustated. Local manufacturers of enameled tiles for walls, although few in number, are in good position to furnish all requirements of French consumers.

C.W.S. Course Completed

A class of twenty-two was graduated July 9 at the Chemical Warfare Service School. Among those graduated were three students sent to the school by the Navy and three sent by the Marine Corps. Lieutenant Commander J. McC. Miller, one of the Navy men, stood at the head of the class. The graduating class was addressed by General Fries and Major Atkisson.

A number of line officers are expected to be members of the next class. Those graduated July 9 were:

Majors Adelno Gibson, C.W.S.; Charles W. Mason, C.W.S. Captains Maurice Barker, C.A.C.; Arthur A. Dearing, C.W.S.; Egmont F. Koenig, C.W.S.; Edward C. McLaughlin, C.W.S.; Hiram F. Plummer, C.W.S.; James W. Rice, C.W.S.; Adrian St. John, C.W.S.; Edmund G. Sties, C.W.S.; Edward Wolesensky.

First Lieutenants John W. Lowe, John G. Shannonhouse, James F. Smith and Alden H. Waitt.

From the Navy: Lieutenant Commanders Glenn B. Davis, U. S. N.; Norman C. Gillette, U. S. N.; Justin McC. Miller, U. S. N. and Lieutenant Charles Shaffer, M. C. (U. S. N.)

From the Marine Corps: Captain Ernest E. Eiler, First Lieutenant John W. McNamara, Second Lieutenant Leslie G. Wellman.

Carbonization Committee Meets

The carbonization committee of the American Gas Association met on July 6 to make final plans for the annual report in the fall. It is planned that the manufacturers' group on this committee will summarize all new methods of carbonization of interest to the gas industry by brief descriptions of the plant and processes. The operating sub-committee will report upon as many plants as can be investigated carefully, showing typical operating results for new plant developments. The low-temperature carbonization sub-committee will give similar attention to methods, results and general prospects for low-temperature carbonization of coal. Particularly it is hoped to have consideration given to the economic possibilities of such systems and a discussion of the place which they will fill in the general fuels work of the country.

J. H. Taussig of the United Gas Improvement Co., Philadelphia, is general chairman. The sub-committee chairmen are: Manufacturers sub-committee, F. G. Curfman, Improved Equipment Co., New York City; operating sub-committee, W. H. Earle, Rochester Gas & Electric Corporation, Rochester, N. Y., and low-temperature carbonization sub-committee, J. D. Davis, Bureau of Mines, Pittsburgh.

Industrial Gas Mask for Ammonia Approved

The first approval of an industrial gas mask for use in ammonia fumes has been issued by the United States Bureau of Mines to the Mine Safety Appliances Co., of Pittsburgh, Pa. The Burrell ammonia mask successfully passed the exhaustive series of tests given by the bureau's chemists in accordance with Schedule 14, "Procedure for establishing a list of permissible gas masks."

The gas mask used during the war by the United States Army was largely developed under the direction of the Bureau of Mines and the Chemical Warfare Service. Since the war the Bureau of Mines has been engaged in adapting and developing the gas mask for industrial purposes and promoting its safe usage.

The Burrell ammonia mask consists of an Akron type, Tissot facepiece that allows breathing through the nose, fitted with a special ammonia canister containing copper sulphate pumice stone mixture devised by G. St. J. Perrott, Max Yablick and A. C. Fieldner for the Ordnance Department of the United States Army. It has been found to give absolute protection in any percentage of ammonia gas which the wearer of a mask can stand without unbearable skin irritation.

The canisters submitted by the Mine Safety Appliances Co. protected successfully against 3 per cent of ammonia at a breathing rate of 64 liters per minute for a period of five minutes. This represents the maximum concentration that anyone is likely to enter, as it has a very strong action on the skin. In a concentration of 2 per cent ammonia and a breathing rate of 32 liters per minute, corresponding to active work, six canisters gave a service period of thirty to forty-one minutes. The requirement for approval is twenty minutes.

Special tests of the facepieces fitted with special canisters were made in 1 per cent of sulphur dioxide gas in air, since sulphur dioxide gives a more severe test for facepiece leakage than ammonia.

Approval 1,401 issued to cover this mask states that the mask is approved for safety, practicability and efficiency in concentrations of ammonia in air not exceeding 3 per cent for short periods of time, as ten minutes, or for periods of twenty to thirty minutes in air not exceeding 2 per cent ammonia, and for proportionately longer periods of time in lower concentrations. The replaceable canisters were approved for use only with approved facepieces and harness.

Permissible ammonia masks under this approval will hereafter bear a plate with the seal of the Bureau of Mines, approval and caution clause to promote safe usage.

Patent Policy of the War Department

Announcement is made that it is the policy of the War Department to encourage the development of military inventions by officers, enlisted men and civil employees. In consideration of assistance to be given by the department in the issue of patents, it will require of inventors no more than a license to manufacture and use their inventions for governmental purposes, thereby reserving to the patentee complete freedom and ownership of the patent in its commercial applications. In special cases of inventions of great military importance, however, provision is made for exclusive Government ownership and the utmost secrecy.

Personal

CHARLES Y. CLAYTON, professor of metallurgy at the Missouri School of Mines, will be at Dr. Howe's laboratory at Bedford Hills, N. Y., during the summer.

Dr. HARRY A. CURTIS, who has been with the International Coal Products Corporation as chief chemist, is now general manager of one of the subsidiaries of this company known as the Clinchfield Carbocoal Corporation, South Clinchfield, Va. In this capacity he will have charge of

the plant and industrial village owned by the corporation and be responsible for the further development and operation of the carbonization plant.

EDWARD A. DIETERLE, who has been assistant chief chemist of the Koppers Co., Pittsburgh, will be the chief chemist of the Chicago By-Product Coke Co. The latter plant will be in operation about Sept. 1 to supply mixed coke-oven and water-gas to the Peoples Gas, Light & Coke Co., as a portion of its city supply.

MARTIN G. GEIGER, Harrisburg, Pa., has become connected with the Klipstein Chemical Co., Charleston, W. Va., as chemical engineer.

M. R. HULL, designing engineer of the Chile Exploration Co., has returned from a three months' trip to the company's South American properties.

Colonel JOHN W. JOYES has been chosen to head the technical division of the Ordnance Department of the Army. Colonel Joyes was prominently associated with the nitrate work of the War Department during the war. Recently he has been head of the artillery division of ordnance. He succeeds Colonel C. L. H. Ruggles, who has been instructed to take the Army War College course.

JULIUS KLEIN, who was appointed by the President as Director of the Bureau of Foreign and Domestic Commerce, to fill the position made vacant some time ago by the resignation of R. S. MacElwee, has assumed his duties. Dr. Klein first came to the bureau in September, 1917, as chief of the Latin American Division. He remained in that capacity until May, 1919, when he was made commercial attaché of the department at Buenos Aires, Argentina. He resigned from that position in October, 1920.

CHARLES V. MCINTIRE has resigned his position as chief engineer of the International Coal Products Corporation to enter the field of consulting engineering in association with A. Stephen Knowles of New York City. Mr. McIntire will specialize in the preparation and treatment of coal.

W. W. ODELL, fuels engineer of the Bureau of Mines, is now in North Dakota, where he will co-operate with Prof. Babcock of the University of North Dakota on an extended series of tests of lignite carbonization. The experimental work will be done in the small lignite coking plant of the university as a portion of the co-operative work of the Bureau of Mines and the university.

Dr. J. H. SHRADER, formerly of the United States Department of Agriculture, Washington, D. C., has been appointed Director of the Bureau of Chemistry and Food, Health Department, Baltimore, Md., entering upon his duties July 1.

WALLACE F. SUPER has been transferred from the Laurel Hill, L. I., to the Syracuse plant of the Atmospheric Nitrogen Corporation.

Dr. ROSCOE THATCHER, who succeeds Dr. W. H. Jordan as director of the New York State Agricultural Experiment Station, located at Geneva, assumed his duties July 1.

N. JULIEN THOMPSON has left the employ of the State of Connecticut Industrial Waste Commission and will be retained by the Standard Rolling Mills Co. of Springdale, Conn., as engineer, in charge of development work on a byproduct lithopone plant.

The annual meeting and election of officers of the American Institute of Fertilizer Chemists was held at Battery Park Hotel, Asheville, N. C., on June 24, and the following officers were elected for the ensuing year: President, Dr. Frank L. Parker, of Charleston, S. C.; vice-president, A. G. Stillwell, of New York City; treasurer, W. J. Gascovne, Jr., of Baltimore, Md.; secretary, S. W. Wiley, of Baltimore, Md.

Obituary

Dr. WALLACE CALVIN ABBOTT, founder and for more than thirty years president of the Abbott Alkaloidal Co., now known as the Abbott Laboratories, died at his home in Chicago, July 4.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, July 15, 1921.

Chemical inquiries increased in certain products during the week and in these lines the volume of business improved. In other directions trading was slow and the market activity was in specialties. It might be described as steady on the average yet devoid of unusual propelling features and free from any radical developments. While there are some contracts being placed for future business, most of the buying is for immediate consumption. Consumers are still afraid that prices have not touched bottom in the more important items regardless of stability of values in several of the big basic chemicals. Any rise in prevailing quotations would attract keen attention, but it may be some time before there is enough confidence in values to inspire free buying for prompt and forward shipments.

CONSERVATIVE TRADING THE RULE

There are so many conflicting interests at work at present that conservative trading seems to be the only method of operating. The drastic decline of values in the past eight months has prompted caution all around. Resistance to selling pressure is more pronounced at present and there are no more signs of forced liquidation. Fundamentally, the market is in a much better condition than it was at the beginning of the year, but the proposed revision of import duties is not inspiring to large business temporarily and the ebb and flow of small orders is to be expected. The steady influx of imported chemicals at prices below those named for domestic goods is a restraining influence on American outlet, but the producers are convinced that this condition will right itself when once the new tariff law becomes effective.

GENERAL CHEMICALS

One of the large chemicals which evoked keen interest during the past few days was *bleaching powder*. Prominent manufacturers of this chemical state that they have received numerous inquiries and have booked several large orders for shipment from works to paper mills. The settlement of the recent strike in paper plants has permitted mills to resume operations and there was an immediate response in the call for bleach. Another item that attracted considerable attention was the offering of German *caustic soda* at \$3.35 per 100 lb., duty paid. Domestic caustic soda has displayed its recent stability on spot. Dealers quote the market on 88-92 per cent *caustic potash* at 5@5½c. per lb., while rumors are current that some business has gone through below the inside figure. Some of the largest distributors say they cannot sell this material under 5½c. per lb. Moderate trading is reported for soap-making requirements, but the general demand is rather slow at present. The opinion is prevalent that prices in this commodity are quite near rock bottom. Small sales of *permanganate of potash*, U.S.P., were reported at 29@30c. per lb., depending upon quantity. Moderate inquiries have recently reached the market for limited lots and sellers have not experienced much difficulty in obtaining the above prices. This product was selling at \$4 per lb. during the war. Prominent sellers of *acetate of soda* quote the market at 4½c. per lb. inside and the general quotation is 4¼@4½c., depending on quantity. The demand has not shown very much activity during the past few days and the call has been chiefly restricted to small lots for actual requirements. Large factors in *bichromate of soda* quote the market at 8@8½c. per lb. Resale material has changed hands at 8@8½c. per lb., according to seller. In most quarters where resale material is handled it is stated that the market looks as though it was thoroughly liquidated. Dealers report sales of standard brands *caustic soda* at \$4@\$4.10 per 100 lb., while scattered transactions for export have been made at \$4.15@\$4.25 per 100 lb. At the works, resale material was quoted at 3¼@4c. per lb., depending upon seller, the inside figure

being for large lots. The contract price is quoted at 3¼c. per lb. basis 60 per cent, f.o.b. works. It was stated that a 100-ton order of German caustic soda was recently booked at \$3.35 per 100 lb. Sales of *chlorate of soda* are reported by prominent factors on the basis of 7½c. per lb. f.o.b. works for prompt shipment. This price is about as low as can be quoted in any direction. There is not much activity to report on *nitrate of soda* and sellers quote 7¼@7½c. per lb. for spot material. Some interests are above these prices, but odd lots are on the market and buyers seem to be interested only in quotations that are on the spot market for immediate requirements. Spot prices for imported *prussiate of soda* were a shade easier and sellers quoted 12@12½c. per lb. The demand for this chemical has not been pronounced during the past week and some sellers have resorted to price shading in an attempt to stimulate business. Quiet trading continues to feature the market on powdered *white arsenic* and sellers state that only odd lots are moving at the present time. Prices range from 6½@7c. per lb. *Red arsenic* is quoted by producers at figures ranging from 12@13c. per lb., according to quantity.

COMPARATIVE LIST OF CHEMICALS DURING MONTH OF JUNE, 1921

Product	High	Low	Close
Acetate of soda, lb.....	\$0.04½	\$0.04½	\$0.04½
Arsenic, lb.....	.07	.06½	.06½
Bicarbonate of soda, lb.....	.02½	.02½	.02½
Bichromate of soda, lb.....	.08½	.08	.08
Bleaching power, lb.....	.02½	.02½	.02½
Carbonate of potash, 80-85%, lb.....	.06	.05	.05
Caustic potash, 88-92%, lb.....	.05½	.05	.05
Caustic soda, lb.....	.04½	.04	4.10-100 lb.

Permanganate of potash, U. S. P., lb.....	.32	.30	.30
Soda ash, 100 lb.....	2.20	2.00	2.10
Sulphide of soda, 60-62%, lb.....	.05½	.05½	.05½
Tartaric acid, lb.....	.30	.28	.29

COAL-TAR PRODUCTS

Producers and sellers in general have little in the way of new developments to report. The consuming demand is irregular, but it is believed that the inquiries in the market show a need of supplies and by going after these business can be done in a small way in domestic quarters. The export business shows little signs of a revival except for benzene. Imports of coal-tar products for the month of May, 1921, amounted to \$401,837, for the corresponding month of 1920, \$634,840. For eleven months ended May, 1921, the total was \$13,732,176, just double that of the corresponding period of 1920, which was \$6,464,047. There were no imports of benzene during the month of May in either 1920 or 1921, but the exports in May, 1921, amounted to 18,102,679 lb., valued at \$788,511, and for May, 1920, 1,483,096 lb., valued at \$97,775. The imports of naphthalene for eleven months ended May, 1920, amounted to 5,358,800 lb., valued at \$139,936, while for the corresponding period of 1921 they amounted to 13,456,830 lb., valued at \$502,490. In comparing the month of May, 1920, with May, 1921, there seems to be about 600,000 lb. less imported this year. Besides the exports of benzene there were other coal-tar distillates valued at \$856,976 in May, 1920, and \$21,228 in May, 1921.

Sellers report a better inquiry, and sales while taking place only in small quantities, are embodying a wider variety of products. Cheap resale lots are fast disappearing from the market. *Benzene* is moving quite steadily and prices are firm at 27@30c. per gal. for the pure and 25@28c. per gal. for the 90 per cent grade. *Naphthalene* is in easy supply, but there is only a little demand noted and prices range from 7@8½c. per lb. In some quarters a fair routine movement is noted in *phenol* with the inside figure heard at 9½c. per lb. Intermediates are gradually picking up and while the demand is confined to small lots, it is nevertheless spreading throughout the list and prices are more steady. *Beta naphthol* continued quiet with the low figure named at 35c. per lb. in some directions. The general quotation ranges from 35@40c. per lb., depending on quantity. *Dimethylaniline* is a shade lower at 38@50c. per lb., depending upon seller. There is little other than a routine movement in *paranitraniline* and prices range from 82@90c.

per lb. Reports from some quarters on *para amidophenol* reflect a steady demand for the base material, and while \$1.50 per lb. is quoted by most sellers, some shading on a firm order is thought quite possible. The hydrochloride is quoted at \$1.60@1.75 per lb., but very little business is being done. The tone of the market in *aniline oil* is steady, although there is still only a small-lot movement of a routine nature. Prices range from 20@26c. per lb. with some producers reporting a limited business around 23c. The demand for *aniline salt* is quiet and only an irregular small quantity of business is reported. Consumers show few signs of coming into the market and prices are a shade lower at 25@28c. per lb.

HIGH AND LOW PRICES IN COAL-TAR PRODUCTS DURING JUNE, 1921

Products	High	Low
Benzene, c.p., gal.....	\$0.27	\$0.27
Cresol, U.S.P., lb.....	.16	.16
Cresylic acid, 97-99%, gal.....	.75	.70
Naphthalene flakes, lb.....	.08	.07
Phenol, lb.....	.11	.10
Solent naphtha, water white gal.....	.25	.25
Toluene, gal.....	.28	.28

Monochlorobenzene, lb.....	.14	.12
Nitrobenzene, lb.....	.13	.12
Para nitraniline, lb.....	1.00	.85

VEGETABLE OILS

Trading in *chinawood oil* was inactive and the undertone covering forward business was barely steady. For spot oil nominal quotations ranged from 14@15c. per lb. A quantity now afloat was offered at 11½c. per lb., c.i.f. New York. July shipment from the Orient closed at 10¼@10½c. per lb., c.i.f. New York. On the Coast 12c. was asked for spot oil in hardwood barrels. The demand for *coconut oil* was quiet and prices in some directions were hardly steady. Manila oil was offered at 7½c. per lb., bulk basis, July-August shipment, c.i.f. Coast, while for tank cars there were sellers at 7¾c. per lb., forward shipments, f.o.b. Coast. Prompt shipment oil on the Coast held at 7½@8¼c. per lb., sellers' tanks. Domestic Ceylon type oil closed nominally at 8½@8¾c. per lb., sellers' tanks, f.o.b. New York. Advices from the Middle West reported a slightly firmer tone in the market for *crude corn oil*, in sympathy with the strength in cottonseed oil, but the actual price changes were very slight. The mills in the West were asking from 5½@5¾c. per lb., sellers' tanks, immediate shipment. With the advance in crude cottonseed, the market for *peanut oil* held firm. Oriental crude sold at 6¼c. per lb., Coast, sellers' tanks, prompt shipment. A sale of one carload of imported oil sold at 6½c. per lb., sellers' tanks, f.o.b. Coast. Domestic oil sold at 7c. per lb., basis prime, f.o.b. mills, Southeast, with numerous bids in the market at 6¾c. Several holders of domestic crude raised their views to 7¼c. per lb., buyers' tanks, f.o.b. mill. A sale of *crude soya bean oil* went

HIGH, LOW AND CLOSE IN VEGETABLE OIL MARKET DURING JUNE, 1921

	High	Low	Close
Castor oil No. 1, U.S.P., lb.....	\$0.10½	\$0.10	\$0.10½
Castor oil, tech., lb.....	.09	.08½	.08½
Chinawood oil, coast, bbl.....	.14	.12½	.13½
Chinawood oil, N. Y. bbl., lb.....	.15	.13	.14
Cocoonut oil, Ceylon, bbl., lb.....	.10½	.10	.10½
Cocoonut oil, Cochin, bbl., lb.....	.11½	.11	.11
Corn oil, crude, bbl., lb.....	.07½	.07½	.07½
Corn oil, refined, bbl., lb.....	.09½	.09¼	.09¼
Olive oil, denatured, bbl., lb.....	1.45	1.35	1.35
Palm oil, lagos, bbl., lb.....	.07½	.06½	.06½
Palm oil, Niger, bbl., lb.....	.05½	.05½	.05½
Peanut oil, domestic, f.o.b. mill, lb.....	.06	.05½	.06
Peanut oil, deodorized, lb.....	.10½	.10	.10½
Rapeseed oil, refined, bbl., lb.....	.92	.88	.88
Soya bean oil, N. Y., bbl., lb.....	.07½	.07½	.07½

through late last week at a shade under 6c. per lb., sellers' tanks, duty free, immediate shipment from the Coast. The market closed nominally at 6@6¼c. per lb., Coast basis, tank cars. Importers now believe that there is a possibility for a resumption of trading in futures, owing to the upward tendency of cottonseed and other edible oils.

The Chicago Market

CHICAGO, July 15, 1921.

There were no new developments in the industrial chemical markets during the past two weeks. A fair volume of small orders was reported in most quarters and inquiries were fair, but no large transactions were noted. Dealers and agents seem to have ample supplies on hand and in general prices are firm with a few exceptions.

GENERAL CHEMICALS

Caustic soda is in a very firm position with supplies light. The ground or flake 76 per cent is quoted at \$4.65@4.75 per 100 lb. and the solid at \$4@4.10. *Soda ash* is moving very well and \$2.60 per 100 lb. for barrels was the best offer noted. *Sal ammoniac* is weaker with continued arrivals of foreign material, and supplies of the prime white granular are available at 7¾c. per lb. for large casks. There is a small demand for *barium chloride* and the white crystals are offered at \$75@\$85 per ton, according to the quantity. There was a somewhat better request for *powdered alum* and several sales were noted at 8@8½c. per lb. *Carbon tetrachloride* is firm, with the inquiry good, holders asking 11@11½c. per lb. for the large drums. *Formaldehyde* is rather lifeless and little business was reported at the present level of 14c. per lb. in barrels.

The alcohol market is in a poor condition and little or no business is reported. A wide range of prices can be obtained on completely denatured and stocks in second hands are heavy. Distillers quote 35c. per gal. drum basis on No. 5 c.p. 188 deg. proof. *Methanol* is in a better condition and small orders were filled for the 95 per cent at 85c. per gal. in drums. *Glycerine* is weak, with the inquiry light, and ample supplies are available at 14¾c. per lb. for the large drums. The bichromate situation lacks new features and the prices are firm with only small quantities moving. *Bichromate of soda* is held at 9@9½c. and *potassium bichromate* at 14c. per lb. *Caustic potash* is moving in a fair way at 6¾c. per lb. for the 88-92 per cent. *Nitrite of soda* is firm and unchanged at 9c. per lb. for single casks. *Hyposulphite of soda* is in good demand and holders are asking \$4.05 per 100 lb. for the pea crystals. *Zinc chloride* is steady and spot goods are offered at 11½c. per lb., although a somewhat better offer was noted on material for prompt shipment from the east. *Zinc sulphate* is quiet and supplies are available at 3½c. per lb.

The list of acids is very quiet with few changes in prices reported. *Acetic acid*, 28 per cent, is moving in a fair way at \$2.60 per 100 lb. in barrels. The *glacial acid* is dead and prices range from 8@11c., according to the quantity and holder. *Oxalic acid* is in good demand and supplies are available at 18c. per lb. The heavy acids are unchanged as to price and are not moving so well. *Sulphuric acid* is still quoted at \$19@\$20 per ton in tank cars f.o.b. works.

VEGETABLE OILS

The only item worthy of attention in this market is *linseed oil*. This item is very firm and dealers report a fairly good movement of supplies to the paint trade. The raw oil is offered at 78c. per gal. and the boiled at 80c. in cooperage.

NAVAL STORES

The feature of this branch of the trade was the sharp advance in the price of *turpentine*. Today this material is very firm and a good inquiry is noted. Dealers are quoting 67c. per gal. in drums and report a satisfactory volume of business. *Rosins* are only in a moderate request and the G and H grades are offered at \$4.50 per 280 lb. in carlots. *Rosin oil* is slow and the price is unchanged at 45c. per gal. for material in cooperage.

The Iron and Steel Market

PITTSBURGH, July 15, 1921.

The general condition of affairs in the steel market is not sensibly changed by last week's announcements of steel price reductions. Most of the reductions thus formally announced were simply recognition of prices previously made by the open market, through the price cutting route. Taking the trade as a whole, the idea of recent years, of there being a fixed price for each steel commodity, all other prices being "cut" prices, is yielding rather slowly, although there have been times in the steel trade when the market price of steel was simply what sellers were getting for it, and the position seems to be a perfectly natural position for a commodity market to occupy.

What is perhaps really significant in the market situation is that there is less talk about "the next reduction" or "the final reduction." The trade seems now to be getting away from the idea that the steel market has simply been moving toward a stable level, one that would be maintained or one from which advances would occur. This means, of course, that expectation has been dwindling that there would be in the not distant future, say within a period of months, one of those steel market phenomena known as "a buying movement," in which buyers changed their tactics and bought farther and farther ahead, being encouraged in this by there being slight price advances from time to time. The outlook now is that for an indefinite time the buying of steel will be merely in keeping with requirements as they develop.

STEEL PRODUCTION

Steel production is at not over about 20 per cent of productive capacity, there having been only a slight downward trend in the past week or two. The average rate of production in June was about 27 per cent. July being traditionally a very dull month in the steel industry, it seems improbable that there will be much if any further decline in production, while an increase can easily occur without there being any great change in general conditions.

A factor that will produce an increase in demand upon the steel mills is liquidation of stocks in the hands of buyers of steel, both of stocks of steel and of manufactures of steel. In the case of the agricultural implement factories the stocks of finished implements are much larger than the stocks of steel. With other manufacturing consumers, as a whole, the balance is probably the other way. The liquidation does not seem to be proceeding very rapidly. In the oil industry there remain some stocks of tubular and other goods, while drilling and other work is very light.

In some quarters predictions are made that the railroads will soon become important buyers, favorably affecting steel mill operations. These predictions seem to be based largely on theory, it being a fact that some men, in most intimate contact with the railroads, refuse to make predictions. The fact may not be as generally known as it should be that the railroads owe the steel mills and some customers of the steel mills quite a large sum of money in the aggregate, and remittances rather than orders are desired first.

It is the common view that the demand upon the steel mills, represented by the rate of production, since almost all orders and specifications received are filled within a very few days, is quite below a normal relation to the general industrial and commercial activity of the country. Of that there is no question, but while the fact of the demand being subnormal in this sense may be quite patent there is no light on the question how long it can remain so. In the past the phenomenon was not observed. Steel mill operations before the war never dropped below about 50 per cent of capacity, and that came to be considered the irreducible minimum. Today's 20 per cent operation is equal to only about 30 per cent operation of the total capacity in existence in 1914.

Pig iron has continued to slide off, declines in the week being about 50c. a ton. The valley market is quotable at about \$21 for bessemer, \$20.50 for foundry and \$19.50 for basic. Freight to Pittsburgh is \$1.96, but it should be noted that basic iron for Pittsburgh delivery, from other sources than the valleys, has been available at 50c. or more below the valley equivalent.

Sulphuric, 66 deg., carboys.....ton		
Sulphuric, fuming, 20 per cent (oleum) tank cars.....ton	21.00 - 22.00	
Sulphuric, fuming, 20 per cent (oleum) drums.....ton	23.00 - 23.50	24.00 - 24.50
Sulphuric, fuming, 20 per cent (oleum) carboys.....ton	31.00 - 32.00	33.00 - 34.00
Tannic, U. S. P.....lb.	.45 - .48	.50 - 1.00
Tannic (tech.).....lb.		.50 - .55
Tartaric, crystals.....lb.		.29 - .30
Tungstic, per lb. of WO.....lb.		1.30 - 1.40
Alcohol, Ethyl.....gal.		4.80 - 5.00
Alcohol, Methyl (see methanol).....		.31 - .36
Alcohol, denatured, 188 proof.....gal.		.38 - .42
Alcohol, denatured, 190 proof.....gal.		.04 - .04½
Alum, ammonia lump.....lb.	.03½ - .03½	.04 - .04½
Alum, potash lump.....lb.	.03½ - .04	.04½ - .04½
Alum, chrome lump.....lb.	.10 - .11	.11½ - .12½
Aluminium sulphate, commercial.....lb.	.01½ - .02	.02½ - .02½
Aluminium sulphate, iron free.....lb.	.03 - .03½	.03½ - .04
Aqua ammonia, 26 deg., drums (750 lb.).....lb.	.07 - .07½	.07½ - .08
Ammonia, anhydrous, cyl. (100-150 lb.).....lb.	.30 - .32	.33 - .35
Ammonium carbonate, powder.....lb.	.08 - .08½	.09 - .10
Ammonium chloride, granular (white sal ammoniac).....lb.	.06½ - .06½	.07 - .07½
Ammonium chloride, granular (gray sal ammoniac).....lb.	.07½ - .08	.08½ - .08½
Ammonium nitrate.....lb.	.07 - .07½	.07½ - .08½
Ammonium sulphate.....100 lb.	2.70 - 2.75	2.80 - 3.00
Amylacetate.....gal.		4.00 - 4.25
Amylacetate tech.....gal.		2.50 - 3.00
Arsenic oxide, (white arsenic) powdered lb.	.06½ - .07	.07½ - .08
Arsenic, sulphide, powdered (red arsenic) lb.	.11 - .11½	.12 - .13
Barium chloride.....ton	59.00 - 59.50	60.00 - 62.00
Barium dioxide (peroxide).....lb.	.20 - .21	.22 - .23
Barium nitrate.....lb.	.07½ - .07½	.08 - .08½
Barium sulphate (precip.) (blanc fixe).....lb.	.04½ - .05	.05½ - .06
Bleaching powder (see calc. hypochlorite).....		
Blue vitriol (see copper sulphate).....		
Borax (see sodium borate).....		
Brimstone (see sulphur, roll).....		
Bromine.....lb.	.41 - .42	.43 - .45
Calcium acetate.....100 lbs.	2.00 - 2.05	
Calcium carbide.....lb.	.04½ - .04½	.05 - .05½
Calcium chloride, fused, lump.....ton	23.50 - 24.00	24.50 - 25.50
Calcium chloride, granulated.....lb.	.01½ - .02	.02½ - .02½
Calcium hypochlorite (bleach powder) 100 lb.	2.15 - 2.25	2.35 - 2.50
Calcium peroxide.....lb.		1.40 - 1.50
Calcium phosphate, tribasic.....lb.		.15 - .16
Camphor.....lb.		.75 - .78
Carbon bisulphide.....lb.	.06½ - .07	.07½ - .08
Carbon tetrachloride, drums.....lb.	.10½ - .10½	.11 - .12
Carbonyl chloride (phosgene).....lb.		.60 - .75
Caustic potash (see potassium hydroxide).....		
Caustic soda (see sodium hydroxide).....		
Chlorine, gas, liquid-cylinders (100 lb.).....lb.	.08 - .09	.09½ - .10
Chloroform.....lb.		.40 - .43
Cobalt oxide.....lb.		3.00 - 3.10
Copperas (see iron sulphate).....		
Copper carbonate, green precipitate.....lb.	.19 - .19½	.20 - .21
Copper cyanide.....lb.		.50 - .62
Copper sulphate, crystals.....lb.	.05½ - .06	.06½ - .06½
Cream of tartar (see potassium bitartrate).....		
Epsom salt (see magnesium sulphate).....		
Ethyl Acetate Com. 85%.....gal.		.85 - 1.00
Ethyl Acetate pure (acetic ether 98% to 100%).....lb.		.50 - .52
Formaldehyde, 40 per cent.....lb.	.13 - .13½	.13 - .14
Fusel oil, ref.....gal.		3.00 - 3.25
Fusel oil, crude.....gal.		1.75 - 2.00
Glauber's salt (see sodium sulphate).....		
Glycerine, C. P. drums extra.....lb.		.15 - .15½
Iodine, resublimed.....lb.		3.65 - 3.75
Iron oxide, red.....lb.		.10 - .20
Iron sulphate (copperas).....ton	19.00 - 20.00	21.00 - 22.00
Lead acetate.....lb.		.11½ - .13½
Lead arsenate, paste.....lb.	.09 - .09½	.10 - .11
Lead nitrate.....lb.		.15 - .20
Litharge.....lb.	.38½ - .08½	.08½ - .09
Lithium carbonate.....lb.		1.30 - 1.40
Magnesium carbonate, technical.....lb.	.09 - .09½	.10 - .11
Magnesium sulphate, U. S. P.....100 lb.	2.40 - 2.75	
Magnesium sulphate, technical.....100 lb.		1.20 - 1.75
Methanol, 95%.....gal.		.77 - .80
Methanol, 97%.....gal.		.80 - .85
Nickel salt, double.....lb.		.12 - .12½
Nickel salt, single.....lb.		.14 - .14½
Phosgene (see carbonyl chloride).....		
Phosphorus, red.....lb.	.45 - .46	.47 - .50
Phosphorus, yellow.....lb.		.35 - .37
Potassium bichromate.....lb.	.11½ - .11½	.12 - .12½

	Carlots	Less Carlots
Potassium bitartrate (cream of tartar), lb.	\$ \$	\$0.30 - \$0.31
Potassium bromide, granular, lb.		.16 - .25
Potassium carbonate, U. S. P., lb.	.35 - .40	.45 - .50
Potassium carbonate, 80-85%, lb.	.05 - .05½	.06 - .07
Potassium chlorate, crystals, lb.	.07½ - .07¾	.08 - .12
Potassium cyanide, lb.		.26 - .28
Potassium hydroxide (caustic potash), lb.	.05 - .05½	.05½ - .06
Potassium muriate, 80% K.C.L., ton	45.00 - 50.00	
Potassium iodide, lb.		2.75 - 3.00
Potassium nitrate, lb.	.09½ - .09¾	.10 - .12½
Potassium permanganate, lb.	.29 - .30	.31 - .32
Potassium prussiate, red, lb.	.30 - .31	.32 - .33
Potassium prussiate, yellow, lb.	.22 - .22½	.23 - .23½
Potassium sulphate (powdered), per unit		1.50 - 1.75
Rochelle salts (see sodium potas tartrate)		
Salammoniac (see ammonium chloride)		
Sal soda (see sodium carbonate)		
Salt cake, ton		23.00 - 25.00
Silver cyanide, oz.		1.35 - 1.38
Silver nitrate, oz.		.40 - .41
Soda ash, light, 100 lb.	2.00 - 2.10	2.15 - 2.50
Soda ash, dense, 100 lb.	2.35 - 2.40	2.45 - 2.70
Sodium acetate, lb.	.04½ - .04¾	.04½ - .05½
Sodium bicarbonate, 100 lb.	2.25 - 2.40	2.50 - 2.75
Sodium bichromate, lb.	.08 - .08½	.08½ - .09
Sodium bisulphate (nitre cake), ton	5.00 - 5.25	5.50 - 6.50
Sodium bisulphite powdered, U.S.P., lb.	.05 - .05½	.05½ - .06
Sodium borate (borax), lb.	.06 - .06½	.06½ - .07
Sodium carbonate (sal soda), 100 lb.	1.90 - 2.00	2.10 - 2.40
Sodium chlorate, lb.	.07½ - .07¾	.08 - .08½
Sodium cyanide, lb.	.19½ - .21	.22 - .30
Sodium fluoride, lb.	.11½ - .12	.12½ - .13½
Sodium hydroxide (caustic soda), 100 lb.	4.00 - 4.10	4.15 - 4.60
Sodium hyposulphite, lb.		.03½ - .03¾
Sodium nitrate, 100 lb.	2.90 -	3.00 -
Sodium nitrite, lb.	.07½ - .07¾	.07½ - .08
Sodium peroxide, powdered, lb.	.25 - .26	.27 - .30
Sodium phosphate, dibasic, lb.	.04½ - .04¾	.05 - .05½
Sodium potassium tartrate (Rochelle salts), lb.	.12 - .12½	.12½ - .13
Sodium prussiate, yellow, lb.		.12½ - .13
Sodium silicate, solution (40 deg.), 100 lb.	1.00 - 1.15	1.25 - 1.40
Sodium silicate, solution (60 deg.), lb.	.02½ - .03	.03½ - .03¾
Sodium sulphate, crystals (Glauber's salt) 100 lbs.	1.50 - 1.75	2.00 - 2.25
Sodium sulphide, fused, 60-62 per cent (conc.) lb.	.05½ - .05¾	.06 - .06½
Sodium sulphite, crystals, lb.	.03½ - .04	.04½ - .04¾
Strontium nitrate, powdered, lb.	.15 - .15½	.16 - .17
Sulphur chloride, red, lb.	.07 - .07½	.07½ - .08
Sulphur, crude, ton	20.00 - 22.00	
Sulphur dioxide, liquid, cylinders extra, lb.	.08 - .08½	.09 - .10
Sulphur (sublimed), flour, 100 lb.		2.25 - 3.10
Sulphur, roll (brimstone), 100 lb.		2.00 - 2.75
Tin bichloride, 50 per cent, lb.	.18 - .19	
Tin oxide, lb.		.40 - .42
Zinc carbonate, precipitate, lb.	.15½ - .16	.16½ - .17
Zinc chloride, gran., lb.	.11 - .11½	.11½ - .12
Zinc cyanide, lb.	.45 - .49	.50 - .60
Zinc dust, lb.	.11½ - .11¾	.11¾ - .12½
Zinc oxide, XX, lb.	.07½ - .07¾	.08 - .09
Zinc sulphate, 100 lb.	3.00 - 3.25	3.30 - 3.50

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude, lb.	\$1.10 - \$1.15
Alpha-naphthol, refined, lb.	1.25 - 1.30
Alpha-naphthylamine, lb.	.35 - .40
Aniline oil, drums extra, lb.	.20 - .26
Aniline salts, lb.	.25 - .28
Anthracene, 80% in drums (100 lb.), lb.	.75 - 1.00
Benzaldehyde U.S.P., lb.	1.50 -
Benzidine, base, lb.	.85 - 1.00
Benzidine sulphate, lb.	.75 - .85
Benzoic acid, U.S.P., lb.	.60 - .65
Benzoate of soda, U.S.P., lb.	.55 - .60
Benzene, pure, water-white, in drums (100 gal.), gal.	.27 - .32
Benzene, 90%, in drums (100 gal.), gal.	.25 - .28
Benzyl chloride, 95-97%, refined, lb.	.28 - .30
Benzyl chloride, tech, lb.	.20 - .25
Beta-naphthol benzoate, lb.	3.50 - 4.00
Beta-naphthol, sublimed, lb.	.70 - .75
Beta-naphthol, tech, lb.	.35 - .38
Beta-naphthylamine, sublimed, lb.	1.75 - 1.80
Cresol, U. S. P., in drums (100 lb.), lb.	.16 - .18
Ortho-cresol, in drums (100 lb.), lb.	.25 - .27
Cresylic acid, 97-99%, straw color, in drums, gal.	.70 - .80
Cresylic acid, 95-97%, dark, in drums, gal.	.65 - .70
Cresylic acid, 50%, first quality, drums, gal.	.45 - .50
Dichlorobenzene, lb.	.06 - .09
Diethylaniline, lb.	1.20 - 1.25
Dimethylaniline, lb.	.38 - .48
Dinitrobenzene, lb.	.26 - .28
Dinitrochlorobenzene, lb.	.20 - .30
Dinitronaphthalene, lb.	.30 - .40
Dinitrophenol, lb.	.35 - .40
Dinitrotoluene, lb.	.27 - .30
Dip oil, 25%, car lots, in drums, gal.	.40 - .45
Diphenylamine, lb.	.60 - .65
H-acid, lb.	1.20 - 1.30
Meta-phenylenediamine, lb.	1.15 - 1.20
Monochlorobenzene, lb.	.12 - .14
Monoethylaniline, lb.	1.75 - 1.85
Naphthalene crushed, in bbls., lb.	.07 - .08½
Naphthalene, flake, lb.	.07 - .08½
Naphthalene, balls, lb.	.08½ - .09½
Naphthionic acid, crude, lb.	.70 - .75
Nitrobenzene, lb.	.12 - .15
Nitro-naphthalene, lb.	.30 - .35
Nitro-toluene, lb.	.16 - .18
Ortho-amidophenol, lb.	3.10 - 3.20
Ortho-dichlor-benzene, lb.	.15 - .20
Ortho-nitro-phenol, lb.	.80 - .85
Ortho-nitro-toluene, lb.	.15 - .20
Ortho-toluidine, lb.	.20 - .25
Para-amidophenol, base, lb.	1.50 - 1.60
Para-amidophenol, HCl, lb.	1.60 - 1.75

Para-dichlorobenzene, lb.	.15 - .20
Paranitroaniline, lb.	.82 - .90
Para-nitrotoluene, lb.	.85 - .95
Para-phenylenediamine, lb.	1.75 - 2.00
Para-toluidine, lb.	1.25 - 1.40
Phthalic anhydride, lb.	.50 - .60
Phenol, U. S. P., drums, lb.	.09½ - .11
Pyridine, gal.	2.00 - 3.50
Resorcinol, technical, lb.	1.75 - 1.85
Resorcinol, pure, lb.	2.25 - 2.30
Salicylic acid, tech., in bbls., lb.	.19 - .22
Salicylic acid, U. S. P., lb.	.20 - .25
Salol, lb.	.80 - .85
Solvent naphtha, water-white, in drums, 100 gal., gal.	.25 - .28
Solvent naphtha, crude, heavy, in drums, 100 gal., gal.	.14 - .16
Sulphanilic acid, crude, lb.	.30 - .35
Tolidine, lb.	1.25 - 1.35
Toluidine, mixed, lb.	.40 - .45
Toluene, in tank cars, gal.	.25 - .28
Toluene, in drums, gal.	.28 - .31
Xylidines, drums, 100 gal., lb.	.40 - .45
Xylene, pure, in drums, gal.	.40 - .45
Xylene, pure, in tank cars, gal.	.45 -
Xylene, commercial, in drums, 100 gal., gal.	.33 - .35
Xylene, commercial, in tank cars, gal.	.30 -

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark, lb.	\$0.24 - \$0.25
Beeswax, refined, light, lb.	.27 - .28
Beeswax, white pure, lb.	.42 - .45
Carnauba, Florida, lb.	.58 - .60
Carnauba, No. 2, North Country, lb.	.25 - .26
Carnauba, No. 3, North Country, lb.	.13½ - .14
Japan, lb.	.16 - .16½
Montan, crude, lb.	.06½ - .06¾
Paraffine waxes, crude match wax (white) 105-110 m.p., lb.	.03 - .03½
Paraffine waxes, crude, scale 124-126 m.p., lb.	.02½ -
Paraffine waxes, refined, 118-120 m.p., lb.	.03 - .03½
Paraffine waxes, refined, 125 m.p., lb.	.03½ - .04
Paraffine waxes, refined, 128-130 m.p., lb.	.04½ - .04¾
Paraffine waxes, refined, 133-135 m.p., lb.	.05 - .05½
Paraffine waxes, refined, 135-137 m.p., lb.	.05½ - .06
Stearic acid, single pressed, lb.	.09 -
Stearic acid, double pressed, lb.	.09½ -
Stearic acid, triple pressed, lb.	.10 - .10½

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on earload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl., 280 lb.	\$5.10 -
Rosin E-F, 280 lb.	5.20 - 5.45
Rosin K-N, 280 lb.	5.70 - 6.75
Rosin W. G.-W. W., 280 lb.	7.35 -
Wood rosin, bbl., 280 lb.	6.25 -
Spirits of turpentine, gal.	.67½ -
Wood turpentine, steam dist, gal.	.60 -
Wood turpentine, dest. dist., gal.	.58 -
Pine tar pitch, bbl., 200 lb.	 - 7.00
Tar, kiln burned, bbl. (500 lb.), bbl.	 - 11.50
Retort tar, bbl., 500 lb.	 - 11.50
Rosin oil, first run, gal.	.35 -
Rosin oil, second run, gal.	.37 -
Rosin oil, third run, gal.	.41 -
Pine oil, steam dist., sp.gr. 0.930-0.940, gal.	\$1.80 -
Pine oil, pure, dest. dist., gal.	1.50 -
Pine tar oil, ref., sp.gr. 1.025-1.035, gal.	.46 -
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla., gal.	.35 -
Pine tar oil, double ref., sp.gr. 0.965-0.990, gal.	.75 -
Pine tar, ref., thin, sp.gr. 1.080-1.960, gal.	.35 -
Turpentine, crude, sp. gr., 0.900-0.970, gal.	1.20 -
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990, gal.	.35 -
Pine wood creosote, ref., gal.	.52 -

Solvents

73-76 deg., steel bbls. (85 lb.), gal.	\$0.41 -
70-72 deg., steel bbls. (85 lb.), gal.	.39 -
68-70 deg., steel bbls. (85 lb.), gal.	.38 -
V. M. and P. naphtha, steel bbls. (85 lb.), gal.	.30 -

Crude Rubber

Para-Upriver fine, lb.	\$0.16 - .17
Upriver coarse, lb.	.09 - .09½
Upriver cancho ball, lb.	.11½ - .12
Plantation—First latex crepe, lb.	.14 -
Ribbed smoked sheets, lb.	.12 - .12½
Brown crepe, thin, clean, lb.	.15 -
Amber crepe No. 1, lb.	.17 -

Oils

VEGETABLE

The following prices are f.o.b. New York for earload lots.

Castor oil, No. 3, in bbls., lb.	\$0.08½ - \$0.09
Castor oil, AA, in bbls., lb.	.10 - .10½
China wood oil, in bbls. (f.o.b. Pac. coast), lb.	.12 - .12½
Cocanut oil, Ceylon grade, in bbls., lb.	.10 - .10½
Cocanut oil, Cochin grade, in bbls., lb.	.10½ - .11
Corn oil, crude, in bbls., lb.	.07½ - .08
Cottonseed oil, crude (f. o. b. mill), lb.	.07 - .07½
Cottonseed oil, summer yellow, lb.	.07½ - .08½
Cottonseed oil, winter yellow, lb.	.08 -
Linseed oil, raw, ear lots (domestic), gal.	.71 - .72
Linseed oil, raw, tank cars (domestic), gal.	.65 - .66
Linseed oil, in 5-bbl lots (domestic), gal.	.73 - .74

Olive oil, Denatured.....	gal.	\$1.35	—	\$1.45
Palm, Lagos.....	lb.	.06 $\frac{1}{2}$	—	.06 $\frac{3}{4}$
Palm, Niger.....	lb.	.05 $\frac{1}{2}$	—	.05 $\frac{3}{4}$
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.07	—	.07 $\frac{1}{2}$
Peanut oil, refined, in bbls.....	lb.	.10	—	.10 $\frac{1}{2}$
Rapeseed oil, refined in bbls.....	gal.	.88	—	.90
Rapeseed oil, blown, in bbls.....	gal.	.94	—	.95
Soya bean oil (Manchurian), in bbls. N. Y.....	lb.	.07 $\frac{3}{4}$	—	
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.06	—	

FISH

Light pressed menhaden.....	gal.	\$0.42	—	
Yellow bleached menhaden.....	gal.	.44	—	
White bleached menhaden.....	gal.	.46	—	
Blown menhaden.....	gal.	.50	—	

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.....	net ton	\$24.00	—	30.00
Barytes, ground, off color, f.o.b. Kings Creek.....	net ton	22.00	—	26.00
Barytes, crude, 88% @ 94% ba., Kings Creek.....	net ton	10.00	—	12.00
Barytes, floated, f.o.b. St. Louis.....	net ton	26.50	—	28.00
Barytes, crude, first grade, Missouri.....	net ton	7.00	—	
Blanc fixe, dry.....	lb.	.04 $\frac{1}{2}$	—	.04 $\frac{3}{4}$
Blanc fixe, pulp.....	net ton	45.00	—	55.00
Casein.....	lb.	.08	—	.10
Chalk, domestic, extra light.....	lb.	.04 $\frac{1}{2}$	—	.05
Chalk, domestic, light.....	lb.	.04	—	.04 $\frac{1}{2}$
Chalk, domestic, heavy.....	lb.	.03 $\frac{3}{4}$	—	.04
Chalk, English, extra light.....	lb.	.04 $\frac{1}{2}$	—	.05
Chalk, English, light.....	lb.	.04 $\frac{1}{2}$	—	.05
Chalk, English, dense.....	lb.	.04	—	.04 $\frac{1}{2}$
China clay (kaolin) crude, f.o.b. mines, Georgia.....	net ton	8.00	—	10.00
China clay (kaolin) washed, f.o.b. Georgia.....	net ton	12.00	—	15.00
China clay (kaolin) powdered, f.o.b. Georgia.....	net ton	18.00	—	22.00
China clay (kaolin) crude f.o.b. Virginia points.....	net ton	8.00	—	12.00
China clay (kaolin) ground, f.o.b. Virginia points.....	net ton	15.00	—	25.00
China clay (kaolin), imported, lump.....	net ton	12.00	—	20.00
China clay (kaolin), imported, powdered.....	net ton	20.00	—	25.00
Feldspar, crude, f.o.b. Maryland and North Carolina points.....	gross ton	8.00	—	14.00
Feldspar, crude, f.o.b. Maine.....	net ton	7.50	—	10.00
Feldspar, ground, f.o.b. Maine.....	net ton	21.00	—	23.00
Feldspar, ground, f.o.b. North Carolina.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. N. Y. State.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. Baltimore.....	net ton	27.00	—	30.00
Fullers earth, f.o.b. Mires.....	net ton	16.00	—	17.00
Fullers earth, granular, f.o.b. Ia.....	net ton	15.00	—	18.00
Fullers earth, powdered, f.o.b. Fla.....	net ton	18.00	—	
Fullers earth, imported, powdered.....	net ton	24.00	—	27.00
Graphite, Ceylon lump, first quality.....	lb.	.07 $\frac{1}{2}$	—	.08

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

BIRMINGHAM—E. W. Barrett, Birmingham, and associates are organizing a new company for the construction of a paper mill in this section. The proposed plant is estimated to cost in excess of \$750,000, including machinery.

California

ORANGE—The California Wire Co., recently organized, is planning for the erection of a new local plant, 80 x 135 ft., for the manufacture of wire products. Louis Koth is president.

Connecticut

STAMFORD—The H. & H. Foundry & Machine Co. is planning for the rebuilding of the portion of its plant, destroyed by fire, July 4, with loss estimated at about \$25,000.

Delaware

YORKLYN—The National Fibre & Insulation Co. has awarded a contract to S. W. N. Worrell, Kennett Sq., Chester, Pa., for the erection of a new 2-story building, 139 x 160 ft. Work will be commenced at once.

Florida

APOPKA—The Florida Insecticide Co. is planning for the rebuilding of its plant, recently destroyed by fire with loss estimated at about \$22,000. J. C. Grossenbacher is manager.

JACKSONVILLE—The American Oil Co. is planning for the construction of a new branch plant for the manufacture of oil products. The company will also build a storage works in the Commodore's Point section.

PALATKA—The United Sugar Corp. has preliminary plans under way for the erection of a new refining plant. H. A. Jones is local manager.

Illinois

CHICAGO—The G-A Ball Bearing Mfg. Co., 3051 West Lake St., manufacturer of steel ball bearings, etc., has completed plans for the erection of a 1-story addition, 210 x 230 ft. at Lake and Albany Sts., estimated to cost about \$65,000. Burett H. Stephens, 300 Old Colony Bldg., is architect.

Indiana

WHITING—Fire, July 4, destroyed a large portion of the local plant of the Standard Oil Co. of Indiana, Indianapolis, with loss including equipment, estimated at close to \$2,000,000.

NOBLESVILLE—The N. O. Nelson Mfg. Co., 928 Chestnut St., St. Louis, Mo., manufacturer of enameled plumbing fixtures, etc., is completing plans for extensions and improvements in its plant at Noblesville, to cost about \$50,000. The enameling furnaces at the works will be improved, and a new power house erected. Victor J. Azbe, 2194 Railway Exchange Bldg., St. Louis, is engineer.

TERRE HAUTE—The Turner Glass Co. is reported to be planning for the rebuilding of the portion of its plant destroyed by fire, July 3, with loss estimated at \$40,000.

ELKHART—The American Coating Mills, manufacturer of coated papers, has awarded miscellaneous contracts for the erection and completion of its proposed new 3-story plant at the foot of Division St., to be 50 x 150 ft., with extension, 50 x 50 ft., estimated to cost about \$600,000 with equipment. It will be known as Plant No. 2. James L. Carey, 208 North Laramie St., Chicago, Ill., is engineer.

ALEXANDRIA—The Lippincott Glass Co. has discontinued operations at its local plant for the summer season. Machinery and equipment will be repaired and improved during the curtailment.

Kentucky

ASHLAND—In connection with the erection of its proposed new plant, the Mayo Oil Service Co. will operate a works for the manufacture of soaps, oils and other specialties. It will be located at Front and Eleventh Sts. John C. C. Mayo is president and treasurer.

Maryland

BALTIMORE—The Adamantex Brick Co. of Maryland, recently organized with a capital of \$1,000,000, has plans under way for the erection of a new plant at Arbutus, Md., for the manufacture of sand-cement bricks and affiliated products. It is proposed to develop a capacity of about 240,000 bricks per day. The company is connected with a concern of like name of New York, operating a plant in Brooklyn. It is represented locally by Blum & Makover, Equitable Bldg.

Massachusetts

MALDEN—The Potter Drug & Chemical Corp. is having plans prepared for the erection of a new 2-story building on Medford St., brick and reinforced concrete, 50 x 85 ft.

ABINGTON—Stone & Keller, Brockton, Mass., have leased a local building on Vernon St., and will install equipment at once for the manufacture of rubber cement and kindred specialties. It is proposed to inaugurate operations at an early date.

Mississippi

GULFPORT—The Gulf Coast Oil Refining Co., recently organized with a capital of \$100,000, has leased a site totaling about 20 acres for the erection of its proposed new plant. Initial work will consist of tank installation. George L. Dodds is president, and Charles T. Madison, vice-president and general manager.

Nebraska

ANTIOCH—The Nebraska Potash Works Co. is planning for the rebuilding of the portion of its plant destroyed by fire, July 2, with loss estimated at about \$250,000, including equipment.

New Jersey

MILLVILLE—The F. C. Wheaton Co., specializing in the manufacture of druggists' glassware specialties, has discontinued operations at its plant for the summer season.

New York

LONG ISLAND CITY—The Mirrorlike Mfg. Co., 203 Eighth St., manufacturer of polishes, has acquired property at the Queens Blvd. and Buckley St., 100 x 140 ft., for the erection of a new 2-story building to occupy the entire site.

HUDSON—The International Cement Co., Boston, Mass., has acquired the property and business of the Knickerbocker Portland Cement Co. The company operates a large mill here.

CORNING—Fire, July 7, destroyed a portion of the plant of the Corning Brick, Terra Cotta & Tile Co., with loss estimated at about \$40,000.

SYRACUSE—The Atmospheric Nitrogen Co., affiliated with the Solvay Process Co. and the Semet-Solvay Co., is planning for the early operation of its new local plant, with initial output to total about 20,000 lb. of anhydrous ammonia per day. This first plant unit will represent an investment of close to \$3,000,000, and will be followed at a later date by a number of other plant units, tentative plans for which have been prepared.

NEW YORK—The B. F. Goodrich Co., manufacturer of tires and rubber goods, with plant at Akron, O., has organized a subsidiary company, to be known as the International B. F. Goodrich Co.; the company will take over all plants of the parent organization located at European points, and in the future will operate the properties. The subsidiary is capitalized at \$10,000,000, with local offices at 1780 B'way.

North Carolina

HENDERSON—J. H. Brodie has commenced the erection of a new 1-story plant, 60 x 100 ft., to be equipped for the manufacture of fertilizer products. It is estimated to cost about \$35,000.

Ohio

CLEVELAND—The Noble Refining Co., 706 Canal Rd., has awarded a contract to the Girard Construction Co., Arcade Bldg., for the erection of its proposed new oil-refining plant at Elk Ave. and East Ninth St., to be 1-story and basement, and estimated to cost about \$85,000. A power house will also be constructed. A. Ritman is president.

Pennsylvania

WILLIAMSPORT—William Ditmar, Williamsport, has tentative plans under way for the erection of his proposed new local plant for the manufacture of composition tile products and similar specialties.

JOHNSTOWN—The Lee Strauss Chemical Co., Vine St., has broken ground for the erection of a new 5-story building, 44 x 165 ft., on Levergood St. The Thiele Construction Co., Johnstown, has the building contract. Edward G. Strauss is president.

Tennessee

NASHVILLE—The Victoria Oil & Refining Co. is planning for the rebuilding of the portion of its plant, used for distilling and other service, with loss estimated at about \$25,000.

MT. PLEASANT—The Phosphates Products Co., recently organized, has plans under way for the erection of its proposed new phosphate works, estimated to cost about \$35,000. The plant will have departments for the manufacture of lume material, ground phosphate rock and kindred products. E. E. Fish is secretary and treasurer. James A. Barr, Mt. Pleasant, is construction engineer for the work.

Virginia

MONEY POINT, PORTSMOUTH—Swift & Co., Union Stock Yards, Chicago, Ill., are reported to be planning for the construction of a new plant on a local site, estimated to cost over \$500,000, for the manufacture of fertilizer products. Tentative plans are being drawn.

FRONT ROYAL—Samuel Wine has leased a tract of local property for the development of lead and silver. Machinery for operation will be installed at an early date.

Washington

TACOMA—The National Coconut Oil Co., Tacoma, is now operating at the former plant of the Columbia Brewing Co., and has remodeled the structure to accommodate the new line of business. Production will be devoted to laundry soaps, washing powders, etc. William Virges is president; D. K. Derrickson is secretary and treasurer.

West Virginia

MORGANTOWN—The University of West Virginia has commissioned Architect Paul A. Davis 3rd, 1713 Sansome St., Philadelphia, Pa., to prepare plans for the proposed new chemical laboratory at the institution, estimated to cost about \$400,000.

Quebec

AMOS—The Frank Blais Co. is planning for the rebuilding of its pulpwood plant, recently damaged by fire, with loss estimated at about \$12,000.

New Companies

THE WATERWAY PAPER PRODUCTS Co., 3221 South Kedzie St., Chicago, Ill., has been incorporated with a capital of \$500,000 to manufacture paper goods. The incorporators are John P. Barnes, Guy C. Baltz and Arthur L. Schwartz.

THE CENTRAL WEST GREASE Co., St. Joseph, Mo., has been incorporated with a capital of \$50,000 to manufacture greases, lubricants, etc. A. B. Snoddy is president, and G. F. Bigelow secretary and treasurer, both of St. Joseph.

CRONKHITE, SANDS & Co., Inc., Boston, Mass., has been incorporated with a capital of 500 shares of stock, no par value, to manufacture chemicals, soaps and kindred products. Leonard W. Cronkhite, 142 Berkeley St., is president and treasurer; Warren Sands is vice-president.

THE PENNIE ANTE OIL Co., Los Angeles, Cal., has been incorporated with a capital

of \$200,000 to manufacture petroleum products. The incorporators are L. P. Jones, R. I. Plomert and Joseph M. Howell. The company is represented by David P. Hatch, 1121 I. N. Van Nuys Bldg., Los Angeles.

THE FRANKLIN PAPER BAG MFG. CO., Woodstown, N. J., has been incorporated with a capital of \$300,000 to manufacture paper bags and containers. The incorporators are James M. Clawson, Woodstown; Frank A. Cabeen, Jr., Haverford, Pa.; and James H. Young, Land Title Bldg., Philadelphia, Pa.

THE NEW JERSEY CHEMICAL & RUBBER WORKS, INC., Newark, N. J., has been incorporated with a capital of \$100,000 to manufacture rubber products, chemicals and affiliated specialties. The incorporators are Meyer E. Gusman, Nathaniel Ginsburg and Jacob Janoff. The company is represented by A. Milton Jacobs, 9 Clinton St.

THE OLD COLONY CHEMICAL CO., Avon, Mass., has been incorporated with a capital of \$5,000 to manufacture chemicals and chemical byproducts. William I. Gay is president, and Howard L. Baker, Kingston, Mass., treasurer.

THE NUTINT CO., Philadelphia, Pa., has been incorporated with a capital of \$25,000 to manufacture chemicals and chemical byproducts. M. A. Weisbard, 202 East Allegheny Ave., is treasurer.

THE COMMON SENSE POLISH CO., Los Angeles, Cal., has been incorporated with a capital of \$10,000 to manufacture polishes and kindred specialties. The incorporators are J. E. Lloyd, H. T. Hurley and L. E. Cummings. The company is represented by Wetherbore, Hoyt & Jones, Title Insurance Bldg.

THE SANITARY REDUCTION CO., 35 Central Savings Bank Bldg., Baltimore, Md., has been incorporated with a capital of \$400,000, to manufacture fertilizer products. The incorporators are Joseph G. Johnson and J. Carroll Dailey.

THE BORREGARD CO., New York City, has been incorporated with a capital of \$10,000 to manufacture pulp and paper products. The incorporators are H. Wessel, A. Olafson and A. Marc Barnes, Jr. The company is represented by Barnes, Chilvers & Halstead, 2 Rector St.

THE M. & B. OIL CO., Hoboken, N. J., has been incorporated with a capital of \$100,000 to manufacture and deal in refined oils. The incorporators are Claude M. Morrison, Jesse M. Parshall and Max Blackman. The company is represented by Tackella, Camby & Stiles, 95 River St.

THE ULTRA CHEMICAL CO., 182 Washington St., Newark, N. J., has filed notice of organization to manufacture chemical specialties. E. Manias heads the company.

THE COLUMBUS FOUNDRY CO., Columbus, Ga., has been incorporated with a capital of \$10,000 to manufacture iron and other metal castings. The incorporators are J. B. Knight, Jr., and C. H. Cox, Columbus.

THE S. P. BRICK & TILE CO., Fresno, Cal., has been incorporated with a capital of \$250,000 to manufacture brick, tile and other burned clay products. The incorporators are W. H. Shields, Fresno; W. D. Trewhitt, Hanford, Cal., and L. E. Hayes, Exeter, Cal.

THE BEACON DRUG & CHEMICAL CO., Boston, Mass., has been incorporated with a capital of \$25,000, to manufacture chemicals, byproducts, drugs, etc. Isaac H. Bernstein, 71 Homestead St., Roxbury, Mass., is treasurer; Joseph Golden is president.

THE METAL MATERIALS CO., Asbury Park, N. J., has been incorporated with a capital of \$125,000 to manufacture metalware products. The incorporators are Roscoe G. Tagle, Frank V. B. Young and Isaiah Matlack, 601 Mattison Ave.

THE NATIONAL HUMUS & CHEMICAL CO., Chassell, Mich., has been incorporated with a capital of \$1,000,000 to manufacture fertilizer products. The incorporators are Claude F. Hancock, Chassell; Roy Herlad and Donald I. L. Baugh, Detroit, Mich.

THE SODDER-RITE CO., New York City, has been incorporated with a capital of \$5,000 to manufacture chemical specialties. The incorporators are L. J. Jones, F. E. Lampe and H. Kleinigeris. M. Gollubier, 255 East 149th St., represents the company.

THE WHITTIER POINT OIL CO., Whittier, Cal., has been incorporated with a capital of \$150,000 to manufacture petroleum products. The incorporators are H. H. Witte, Fred G. Phillips and L. F. Ranker, all of Pomona, Cal. The company is represented by E. B. Coil, attorney, Santa Monica, Cal.

THE INTERLOCKING TILE & SEWER PIPE CO., Indio, Cal., has been incorporated with

a capital of \$250,000 to manufacture sewer pipe, tile and other burned clay products. J. A. Gordon is president; J. A. Nelson, vice-president; and J. W. Wilson, treasurer.

THE HOPKINS MASTER CLEANER, INC., Boston, Mass., has been incorporated with a capital of \$20,000 to manufacture cleansing compounds, and kindred products. Alfred Hopkins is president; Howard Knowles, 13 Waterhouse St., Cambridge, Mass., is treasurer.

THE WIS CHEMICAL & DRUG CO., Utica, N. Y., has been incorporated with a capital of \$10,000 to manufacture chemicals and affiliated products. The incorporators are C. C. Allison, P. M. Risinger and C. S. Horsburgh. H. D. Williams, Utica, represents the company.

THE RIVERSIDE BAPTISTE OIL CO., Los Angeles, Cal., has been incorporated with a capital of \$500,000 to manufacture petroleum products. The incorporators are M. W. W. Reitz, J. Sickman and W. H. Dehm, California Bldg.

THE AMERICAN LEATHER MFG. CO., 166 Tichenor St., Newark, N. J., has filed notice of organization to manufacture leather products. John Lipp, 36 Boyd St., heads the company.

THE MIT-SHEL STAMPING & MFG. CO., 510 Jersey St., Quincy, Ill., has been incorporated with a capital of \$50,000, to manufacture stamped metal goods. The incorporators are Edward H. Mitchell, Theodore Schell and William Spohr, Jr.

THE PATUXENT GUANO CO., 407 Vickers Bldg., Baltimore, Md., has been incorporated with a capital of \$75,000 to manufacture fertilizer products. The incorporators are Harry T. Deford, Carroll W. Clark and William E. Gardner.

THE BOONTON CHEMICAL CORP., New York City, has been incorporated with a capital of \$100,000 to manufacture chemicals and chemical byproducts. The incorporators are J. Michaels, H. M. Cassidy and A. M. Hamburg, 63 Wall St.

THE ARDEN CHEMICAL CO., New York City, has been incorporated with a capital of \$500,000 to manufacture chemicals and chemical byproducts. The incorporators are F. O'Leary, F. Delaney and B. Marks, 320 B'way.

THE HIDECKER BRICK CO., Los Angeles, Cal., has been incorporated with a capital of \$10,000 to manufacture brick and other burned clay products. The incorporators are G. C. Hidecker, Charles W. DeWitt and William Lewis, 504 Bryson Bldg.

THE BERG CHEMICAL CO., New York City, has been incorporated with a capital of \$50,000 to manufacture chemicals and chemical byproducts. The incorporators are H. M. Monness, J. Fischer and L. Goldberg. The company is represented by J. Wilzin, 35 Nassau St.

Capital Increases, etc.

THE AMERICAN TANNING CO., 1282 West North Ave., Chicago, Ill., manufacturer of leather products, has filed notice of increase in capital from \$50,000 to \$100,000.

THE MUTUAL CHINA CO., Indianapolis, Ind., has filed notice of increase in capital from \$100,000 to \$200,000.

A petition in bankruptcy has been filed against the ATRIEN CHEMICAL WORKS, 75 John St., New Brunswick, N. J. The liabilities are stated at \$100,000, and assets \$40,000.

THE DESMOND CHARCOAL & CHEMICAL CO., Detroit, Mich., has filed notice of dissolution under state laws.

THE PRESTO CHEMICAL CO., Detroit, Mich., has filed notice of increase in capital from \$25,000 of \$150,000.

THE CENTRAL PENNSYLVANIA OIL CO., Nazareth, Pa., has filed notice of increase in capital from \$200,000 to \$600,000.

THE BECKER PAPER CO., Fort Wayne, Ind., has filed notice of increase in capital from \$50,000 to \$100,000.

THE CENTRAL GLASS CO., Louisville, Ky., has filed notice of increase in capital from \$1,000,000 to \$1,250,000.

THE AMERICAN EAGLE RUBBER CEMENT CO., 3026 South La Salle St., Chicago, Ill., has filed notice of change of name to the Rubber & Cements Co., Inc.

THE NOVELTY LEATHER WORKS, Jackson, Mich., has filed notice of dissolution under state laws.

THE OIL CITY BRASS WORKS, Neaumont, Tex., has filed notice of increase in capital from \$5,000 to \$50,000.

Manufacturers' Catalogs

THE C. W. HUNT ENGINEERING CORP., New York City, calls attention to a four-page booklet on self-aligning all steel troughing belt conveyor idler.

THE READING IRON CO., Reading, Pa., calls attention to Bulletin 2, in which is described, in as simple a manner as possible, the structural difference between wrought iron and steel and their relation to the field of welded pipe. The bulletin has been written to interest the layman as well as the engineer.

HARBISON-WALKER REFRACTORIES CO., Pittsburgh, Pa., announces a leaflet on Metalkase Magnesite Brick for Open Hearth Furnaces.

THE BRITISH ALUMINUM CO., LTD., has published a booklet on "The Casting of Aluminum" which contains information of interest to foundrymen, such as proper mixtures for common aluminum castings, melting practice, precautions in molding, shrinkage allowances, finishing and testing.

THE THWING INSTRUMENT CO., Philadelphia, Pa., desires to announce Bulletin 10. This treats of Type A thermoelectric pyrometers, temperatures from 100 deg. C. (200 deg. F.) to 1,600 deg. C. (2,900 deg. F.), base metal couples in three alloys, and platinum couples for highest temperatures. It describes full equipment and furnace mountings, such as protection tubes, junction boxes, selector switches and high resistance galvanometers, both indicating and recording.

THE WILL CORP., Rochester, Mass., has recently published two bulletins. The first, entitled "Water Stills," presents an outline of laboratory stills now in use and goes into the merits of the various makes and types. The second, entitled "The Ion-O-Meter," is a descriptive pamphlet on the measurement of hydrogen ions and the practical application of the Ion-O-Meter to industrial and laboratory problems.

THE WEBSTER MFG. CO., Chicago, Ill., in its June, 1921, issue of "Webster Method" has illustrated articles on "Perkins Pivoted Bucket Carrier in a Modern Cement Plant," "Conover-McHenry Grain Elevator," and "A Five-Track Steel Coal Tipple."

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY's summer meeting will be held at Canton, Alliance, Sebring and East Liverpool, Ohio, July 25 to 27. Headquarters will be at the Hotel Courtland, Canton, Ohio.

AMERICAN CHEMICAL SOCIETY, THE SOCIETY OF CHEMICAL INDUSTRY and the American Section of the latter society will hold a joint meeting in New York, Sept. 6 to 10.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in Lake Placid, N. Y. Sept. 29 and 30, and Oct. 1.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its fall meeting at Wilkes-Barre, Pa., Sept. 11 to 17.

AMERICAN MINING CONGRESS AND NATIONAL EXPOSITION OF MINES AND MINING EQUIPMENT will hold its twenty-fourth annual convention in the Coliseum, Chicago Oct. 17 to 22.

AMERICAN SOCIETY FOR STEEL TREATING will hold its third annual convention and exhibition Sept. 19 to 24 at Indianapolis.

THE NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SEVENTH) will be held during the week of Sept. 12 in the Eighth Coast Artillery Armory, New York City.

NEW JERSEY CHEMICAL SOCIETY has discontinued meetings for the summer and will resume them in October.

SOCIETY OF CHEMICAL INDUSTRY (BRITISH) at the invitation of the Montreal section will hold its annual meeting in Montreal and other Canadian cities during the week of Aug. 29, 1921. Details will be printed in this magazine from time to time.

SOCIETY OF INDUSTRIAL ENGINEERS will hold its fall meeting at Springfield, Mass. Oct. 5 to 7.

TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its fall convention with the American Pulp and Paper Mill Superintendents' Association, at Washington, Philadelphia, Spring Grove, York, York Haven, Pa., and Wilmington, Del. Oct. 18 to 20.

Number 4

A Serious Economic Problem

EUROPE is now offering to help the United States obtain the sum due under reparation arrangements for actual destruction of American property by Germany. The effort appears to be to assist the United States in getting about three-fourths of a billion dollars due its citizens in order that the United States will in turn assist Europe in collecting the 70 billion payable to the Allies under the treaty. Despite its apparent selfishness, the attitude appears to be diplomatic and fair to the United States. However, underlying all this there is an economic problem of vital significance to chemical as well as other industries.

Already the effort of Germany to meet its financial obligations has resulted in a curtailment of its luxury imports which is proving to be almost fatal to the French wine industries. One famous international statesman has also ascribed the British coal-mine strike directly to the reparation requirement that Germany supply given tonnages of coal to France, Italy, Belgium and others. If so early in the plan two large industrial disasters are caused by compliance with treaty obligations, what can we expect when Germany is well under way in the effort to meet the total obligation of 70 billion dollars?

That this question is of industrial importance, as well as of banking or credit significance, at once appears when we realize that the payment must be made in goods. It cannot be made in money or credit of any sort whatsoever.

Germany recognizes one economic principle and may undertake to apply it in the chemical industries to American disadvantage. This principle is that only a small percentage surplus above the market demand often, if not invariably, results in a large decrease in market prices. What would happen, for example, in the American chemical industry if Germany would see to it that there were always available in the United States markets about 10 to 15 per cent more of a particular chemical than the market was currently able to absorb?

That Germany may be quite capable of this, both industrially and morally, is well recognized.

Presumably the liquidation of credits and the restoration of buying power in the United States will proceed surely, even though slowly, to better times. It is well known that agriculture, representing perhaps one-fourth of the population, and labor out of work, representing with its dependents 10 or 15 per cent more, cannot buy much beyond the bare necessities right now. But times will improve even without the artificial stimulant of legislation, subsidy or governmental co-operation. We can expect something like normal relationships.

On the other hand, we can be sure that Germany cannot last indefinitely on a basis which provides from the Government a subsidy for industry to the extent

of a billion and a half dollars per year gold (figuring the mark at five or six cents). To continue that scheme indefinitely would be lifting oneself by one's own economic boot straps, a thing which does not work in economic affairs any better than in physics. When the subsidy is eliminated, the relationship between Germany and the rest of the world will be more favorable than now to the rest of the world.

In the meantime the main essential for America is recognition of the need for better technology in all processes, closer industrial co-operation all the way from resource to user, and plain hard work.

The Bottom of The Chemical Market

IN DANGEROUS channels the wise skipper takes many soundings. To steer a safe course down the harbor, he must occasionally have an answer to the important question, How near the bottom are we? So, too, the course of the buyer or seller in the chemical market is influenced by similar considerations. He wants to know: How near the bottom are our chemical prices? How do chemicals stand in relation to the products of other industries? Has the process of deflation been completed?

Fortunately, some "soundings" recently made by the Department of Commerce may be of help in answering these perplexing questions. The price indexes, compiled in connection with the monthly studies of industrial movements, show the relative changes in the wholesale prices of chemicals and drugs during 1920 and the first five months of 1921 and afford a valuable means of comparing these articles with other commodities of commerce.

Using the average for 1913 as a base of 100, the relative index for the wholesale prices of chemicals during the first three months of 1920 was 197, for the second three months 215, for the third 218, and for the fourth 204. The maximum for the year was reached in September, and since that time there has been a gradual and continuous falling off, until for May, 1921, an index of 166 is reported. This means, in other words, that during that month the particular chemicals and drugs studied were selling for two-thirds more than in 1913.

How then do chemicals compare with other commodities? The price indexes during the same month of May, 1921, were 117 for farm products, 133 for food, 138 for metals, 181 for clothing, 194 for fuel, 202 for building materials, 263 for housefurnishings, and the average for all was 151. Thus it would appear that the prices of chemicals have fallen somewhat less than those of metals or food products, but are nevertheless at a level comparable with the average for all commodities. Building materials, house furnishings, clothing and fuel, all of which directly affect the consuming public,

remain at higher levels and apparently have not yet taken their proportionate share in the general process of deflation.

These price indexes do not give us an answer to all our inquiries, but they are soundings which should not be disregarded as we are approaching the bottom of chemical prices.

Metallurgical Literature

IN RESPONDING to the Fritz Medal Award, Sir ROBERT HADFIELD made a brief address of thanks, which was supplemented by the distribution of printed pamphlets, appropriate to his desire to convey his high appreciation of the honor. In this pamphlet, after a brief account of his discoveries in alloy steels, for which the medal was given, and the influence of such special steels on the advancement of science, Sir ROBERT passes on to a consideration of the history and works of the Royal Society since its incorporation 260 years ago. He also remarks that the quality and amount of literature in a particular branch of science generally show the relative position it occupies in the world.

This is well illustrated in the science of metallurgy. Starting with AGRICOLA there is with a few exceptions little contained in the books of the chief writers of metallurgy up to 1880 which is of present value, even though the list comprises such authors as DUD DUDLEY (1665), REAUMUR (1722), SWEDENBORG (1734), RINMAN (1782), BERTHOLET (1789), BERZELIUS (1833), DAVID MUSHET (1840), FARADAY (1842), PERCY (1861), HOLLEY (1865), WHITWORTH (1866), GRUNER (1872), and LEDEBUR (1877). Aside from building a sure foundation of chemical analysis, and producing PERCY'S admirable treatises on practice, the preceding years had merely constructed a body of empirical rules-of-thumb, discovered by the method of trial and error. Too often such a discovery was hid within an iron-works and closely guarded as a trade secret, until it was found that everyone else had discovered the same thing.

The decade 1875-1885 witnessed the renaissance of metallurgy. That marvellous series of mechanical appliances which have revolutionized blast furnace practice, steel making and fabricating were devised and put into use. The invention of manganese steels opened a vista of possibilities in alloying which will never become exhausted. Men turned to the physicist and borrowed his microscopes and electrical indicators, and leaned more heavily upon the familiar chemist. But best of all, the profession profited immeasurably by a long list of notable contributions to the *Transactions* of the British Iron and Steel Institute, and the American Institute of Mining Engineers. Indeed, the literature as represented by texts on General Metallurgy and on its specialized branches, has not yet had a chance to overcome the long lead established by periodical literature, represented by society transactions and the technical press. Practice is advancing by such leaps and bounds that "book knowledge" may be permanently outdistanced.

Tens of thousands of metallurgists throughout the world are devoting their attention to scientific and practical metallurgy, and smaller societies now abound. And all this has come about in but 50 years! One wonders what would have been the situation without a vigorous and prolific literature, available to the student young or old, who is intent upon widening his knowledge and skill.

Time to

Change Doctors

DR. POLITICS prescribed an old remedy for a new ailment and a great many people are becoming skeptical of its efficacy. The tariff in the old days was the Republican panacea for all industrial ills but with the changed industrial conditions surrounding our present international situation, it is beginning to be apparent that the time has arrived to change doctors. We regard it as a sign of the times, therefore, that the Senate may be asked to pigeon-hole the tariff bill just passed by the House, and we hope that it will not be revived until the public can make certain that there is not a better and more constructive way to meet the situation.

Tariff revision has been under way for almost a year, and while there has been a gradual and growing opposition, most of us have been content to wait in hopes that somehow and in some way the Ways and Means Committee would report out some wonderful measure that would accomplish the miraculous. The failure of the emergency bill to relieve the plight of the farmers caused many to lose faith in the tariff. And finally the Fordney bill with its radical rates and objectionable features and the high-handed manner in which it was forced through the House, have aroused a nation-wide storm of protest and disgust.

The failure of the dye bill is of most concern to the chemical industry even though our views may differ as to the need for tariff revision at this time. CHEMICAL & METALLURGICAL ENGINEERING has always taken the stand that a complete and well-balanced dye industry is essential to this or any other country concerned with its national defense. Whether or not an embargo is necessary to accomplish this, we can not say, but we do believe that the industry warrants more than usual consideration. If this is to be received from the Senate, the industry must see that many false charges are answered and many unfavorable impressions corrected.

Princeton

In the Saddle

AND now comes Princeton with its school of engineering, four years for a bachelor's degree and one year more for that of engineer. The course is to include a good grounding in physics, chemistry, mathematics, languages, literature, philosophy, economics and sociology. The young man is to achieve, if teaching can give to him, a broad outlook on everyday problems; and the endeavor, according to the announcement made in the July 15 number of *Science*, will be to make an engineer rather than a specialist. Professor ARTHUR M. GREENE, JR., of the Rensselaer Polytechnic Institute is to be dean of the new school and professor of mechanical engineering. He will take up his duties in the fall of 1922.

It's curious, and there's a touch of comedy in it withal, that a considerable group of self-styled humanists, like cherubim and seraphim continually do cry over these developments. That engineering, or the use of science, should enter into higher education as one of its constituent features seems to them the end of intellectual joy. What they fail to recognize is their own modernness in presenting their views. They are shining examples of the defects of modern education for the reason that they are narrow specialists. They weep like children for more and more dead languages and they lack the art to make them alive.

Let us analyze the situation in regard to Greek and Latin, the teaching of which has been going on for a very long time and over which there is the most continuous rumpus. We start as boys, learning declensions and conjugations in Latin and after a year of memorizing we begin with CAESAR'S Commentaries. From the standpoint of human history these looting expeditions are not of prime importance, but the study is not even pursued as history; it is followed as an almost (to the boy) interminable series of exercises in Latin Grammar. Then comes VIRGIL, about 20 lines a day, again with no thought of the legends, the history, the poetry or anything else but the letter without the spirit of the thing. About this time the boy starts with Greek, and XENOPHON'S interesting history is used solely for parsing lessons; and then comes HOMER with the same story better told in Greek than VIRGIL told it in Latin, and this again is seldom much more than a series of parsing lessons. So we go on as boys with parsing lessons in Latin and Greek for about twelve years—and at the end of that time we do not know either the language or its literature.

If we were to teach science that way, without any purpose beyond "the mental exercise" of so much memorizing—there wouldn't be any science. But if the Latin class were to study Latin as a living thing and then even in secondary schools address itself to rendering into English excerpts from the great store of mediaeval records, the boys themselves would get a sense of research, of discovery, of the service of learning—and they would have a working understanding of the language. We can recall the day when the learned clergyman who could converse in Greek was a distinguished scholar. That day is past. Nearly every peanut vendor on the street can converse in Greek. Not very elegant Greek perhaps—but it is Greek. By less worry about the irregularities of verbs and more study of the classic Greek drama as literature and as great cartoons of life, students would acquire the very qualities of mind, would grasp the relations of cause to effect and effect to cause, would sense the inviolability of Nature's laws, and know the fundamental truths which underlie human intercourse that men of science most urgently need.

We urge upon the moaning company of pseudo-classicists the merit of drying their tears. Princeton has not fallen from grace. Engineering has become a part of the life of today. It is not a substitute for history or philosophy or the study of mankind. Engineering alone does not give a man a liberal education—nor does a knowledge of Greek give culture to the peanut wallah. The greatest effort of present day, earnest men of science is toward making their successors persons of large understanding and culture, and above all things to help them develop into men of character so that they may fashion their careers unto righteousness. But more and more the fact is being brought out that engineering is needed in daily life. We need it if we intend to do things and most sound boys, thank GOD, want to do things. We need it also in archaeology and in the study of human history. It is the index of civilization.

The Greeks, by the way, were excellent engineers and the Romans copied from them. In the days of the renaissance—well, there was LEONARDO DA VINCI. After a letter of several pages in which he told in detail to the Pope many of the things he could do, including almost every branch of engineering then known, he concluded with the sentence, "I can also paint."

Fluctuations and Drifts in Prices

WE HAVE all seen by experience that commodity prices fluctuate. They did that even before the war showed us how violently they could move upon sufficient provocation. There has been question, however, as to the general drift, that is, the general tendency when a smooth curve is drawn through the graph plotted from recorded prices.

The statistician of the Russell Sage Foundation, Dr. RALPH G. HURLIN, has carried back to 1810 an index number of commodity prices and back to 1820 the average wage rate of common labor and a composite wage rate of five classes of artisans—carpenters, house painters, machinists, blacksmiths and compositors. This information is definite and useful. The graph of wholesale commodity prices, from 1810 to 1920, is hardly what one would expect. The striking thing is not a general trend or drift. The impressive thing is three immense peaks, of approximately equal height, one for our war of 1812, or rather our little branch of the Napoleonic wars, a second for the Civil War and a third for the year 1920. After 1815 and 1865 prices showed a generally recessive trend for approximately 30 years in each case. The general drift is a trifle difficult to pick out. The trough between 1890 and 1900 is considerably lower than the trough between 1840 and 1850, but on the other hand there is but a slight ascent in the 15 years or so before the Civil War while there is rather a sharp ascent between 1896 and 1914. Certainly the last war did not forecast its shadow in that manner.

However, one man's composite or budget is not another man's. Timber would certainly show a general sweep upwards in the past century while watches, up to the time of the watch that made the dollar famous, would show an equally impressive downward trend. The proper generalization probably is that on account of the increasing volume of media of exchange, the trend of values is upward over long periods while improvements in the art of producing many things exerts an influence in the opposite direction, and the two may balance or be slightly out of balance according to the selection of articles that go to make up one's weighted average of "commodities in general."

Dr. HURLIN'S wage showing, on the other hand, admits of no argument. The trend was almost continuously upward from 1820 to 1910, the chief irregularity being a bulge at the time of the Civil War, most of which came off in the industrial depression of 1873-8. Wages approximately tripled from 1820 to 1910. The recent war bulge makes almost a vertical line in the graph and of course that peak is going to come off. A very interesting feature of the showing is that the artisans' average ran quite uniformly at about 80 per cent above the common labor rate, and approximately that percentage is likely to be restored.

Counting out the influence of wars, then, there does not seem to be any very marked drift in commodity values, measured by gold, over long periods of time. Wages and salaries have a strong drift upward, which means that relative to the earnings of the individual, commodity prices trend downward, as a result of improvements in methods and appliances. But the greatest thing of immediate concern is that in two conspicuous cases, one 56 years ago and the other more than a century ago, it took fully 30 years for prices to recede completely from their peak. We had a precisely similar peak in 1920.

Italian Chemical Industries

FROM OUR SPECIAL CORRESPONDENT

GENOA, Italy, June 30, 1921.

SOME recovery in foreign exchange took place during June that averted a further reduction in many prices, despite the continuance of the crisis in all industries and the consequent financial difficulties. These caused the chemical industrials at a meeting held in Milan to cancel last November's agreement with their employees to give three months' notice in case of dismissals. The representatives of the labor organizations objected and it was agreed to give the months of July, August and September as notice to the workpeople and to discuss new agreements in October. The shortage of English coal continued, which was in many cases made up by American, Belgian and French coal. The shortage had little effect, owing to the exceedingly low demand for combustibles on the part of industry in general and to the reduced maritime traffic.

ITALIAN MATCH INDUSTRY

The Italian match industry during June went through a very severe crisis, caused by the Italian government failing to draw several large lots of matches and by the fact that the government abolished the monopoly existing during the war too late to prevent other nations invading the foreign markets which Italy formerly supplied. The Italian phosphorus match industry dates from 1831, when wood matches were manufactured for the first time in a works established at Empoli. In 1894 the industry was subjected to a special tax that brought an income of 7,000,000 lire to the Italian government.

ITALIAN QUININE MANUFACTURE

The extraction of quinine and the working of quinine salts was tried in Italy, but till the war the infant industry was suffocated by German competition which by selling under cost killed Italian endeavor in this direction. The government has now undertaken the production of quinine and of its different salts in a works of its own and is also trying to get plantations of cinchona in other countries so as not to be obliged to depend for its raw materials on foreign markets. Quinine and its salts are of great importance to Italy and its colonies where these products are largely employed in combating malarial fevers.

PROHIBITION ON IMPORTATION OF DYESTUFFS

A law has been promulgated prohibiting the importation of dyestuffs from any source whatever. This law gives the Minister of Finances power to grant individual importation permits for products which cannot be produced in Italy or which cannot be produced in sufficient quantity.

DEVELOPMENTS IN HYDRO-ELECTRIC PLANTS IN THE SILA PLAINS

There is much activity in all parts of Italy for increasing the electric energy obtained through water power. Work is being conducted with great intensity on the high Sila plains, where construction has been begun on a large dike which will make possible the utilization of a large artificial lake formed by abundant waterfalls. It is expected that this will supply energy for the electrification of all the railways and industries in southern Italy. Powerful auto lorries are used to

convey the construction materials from Cotrone, Catanzaro and Cosenza.

A NEW HYDRO-ELECTRIC COMPANY

A recent decree authorized the formation at Unide of a new firm of great importance for the whole region north of the Veneto. This firm, bearing the name of Forze Idrauliche del Friuli, is authorized by the government to utilize all the hydraulic forces of the River Tagliamento, its effluents, and of any other river in the region. The company will undertake the construction of electric plants and provide electric energy for them. No limit is placed on its capital, and some of the most important banks will finance it.

ITALIAN FERTILIZER NECESSITIES

Owing to the ground having suffered impoverishment in phosphorus during the war, when the peasant neglected his fields, reducing or discontinuing entirely the treatment of them with fertilizers, a campaign has been started for an extensive use of superphosphates during the next season. It is pointed out that the consumption of phosphorus, which was 1,000,000 tons annually before 1914, fell to 500,000 tons during the war, rising to only 600,000 tons in 1918 and 650,000 tons in 1920. The limited yield of the Italian works during the first months of this year left no stocks on hand, but arrivals of superphosphates were very fair, reaching 56,485 tons in March and 47,697 tons in April.

ITALIAN SULPHUR INDUSTRY

The Italian sulphur industry suffered during June in consequence of the wave of reduction that affected all other industries. The sales of the nine months ended in April last reached only 140,000 tons, against 206,000 tons during the twelve months preceding. Up to nearly the beginning of this century Sicily had a world monopoly as regards sulphur. However, after the discovery of the Louisiana sulphur mines the situation changed completely, and a great deal of business was lost through the competition of these mines, which had the advantage of being more modernly worked, while in Sicily little change had been introduced and old-fashioned methods of extraction were used. At present Italian sulphur is competing with difficulty against the American product not only in the American market but also in Europe. Through the initiative of the proprietors of Sicilian sulphur mines a new firm has been founded at Palermo having a capital of 3,000,000 lire, and sulphur refineries close to the sites of extraction will be built.

Italian Imports and Exports During 1920

The values of imports and exports for 1920 by great groups of commodities are given in the following table:

Group	Imports —Millions, Lire—			Exports —Millions, Lire—		
	1913	1919	1920	1913	1919	1920
Raw materials.....	1,387	5,302	5,014	360	758	989
Semi-manufactured materials..	705	2,842	3,249	591	2,153	2,269
Manufactured articles.....	851	2,616	3,365	798	2,191	3,292
Foodstuffs and live animals...	703	5,864	4,233	762	963	1,253
Total.....	3,646	16,624	15,861	2,511	6,065	7,803

In the matter of exports more or less notable gains have been made to all countries, with the exception of France and Tripoli, the largest increases being to the Argentine Republic, Switzerland, the United States, Brazil, Egypt, British India, and Spain, in the order named.

BRICK KILNS ARRANGED FOR BYPRODUCT RECOVERY

Hardwood-Distillation Industry—I

Importance of Hardwood-Distillation Products in Industrial Life—Periods in the History of This Industry —Commercial Methods of Distillation—Relation Between the Composition of Wood and Its Distillation Products

BY L. F. HAWLEY*

THE United States is by far the greatest producer and consumer of wood-distillation products. The only other countries which have an output large enough to make a showing in a table of statistics are Austria, Germany and Canada. The following table gives the estimated annual production of the four countries for the period just previous to 1914:

	Acetate, Tons	Methanol, Gal.	Wood, Cords
United States.....	80,000	9,000,000	1,000,000
Germany and Austria ¹	25,000	2,800,000	300,000
Canada.....	8,500	950,000	110,000

Aside from these countries, England, Sweden, France, Japan and Italy are known to have small wood-distillation industries. During the war great efforts were made in England to develop this industry, and several small plants were built; but the combined output of these plants would not be greater than that of one medium-sized plant in this country. In 1917 the output of methanol and acetate of lime in Sweden was about equal to the output of a single plant with a capacity of 50 cords of hardwood per day. Sweden has several well-built wood-distillation plants, and the explanation of the small output is that hardwoods are not abundant and resinous wood is the raw material commonly used, resulting in a low production of methanol and acetic acid. In 1915 Japan had developed an industry which gave an output equivalent to about one 50-cord plant. France has had a small industry of this kind for some

time, and Italy has been doing some preliminary work along this line. A very small industry started in Argentina, and shipments of wood-distillation apparatus to India from this country have been recently reported. Government officials and representatives of private companies have been sent to this country from Australia to investigate wood-distillation for the purpose of establishing plants in that country, but no construction has been started as yet.

The large capacity of the wood-distillation industry in the United States is probably due to the great supply of good-quality hardwoods available for this purpose, as well as to the increasing demand for the products.

The immense supplies of hardwood in the tropics have not been touched yet for the purpose of wood-distillation and we have no information in regard to their suitability.

IMPORTANCE OF HARDWOOD-DISTILLATION PRODUCTS IN INDUSTRIAL LIFE

Charcoal.—Charcoal has been known and used as a fuel since prehistoric times, but at present it has only special fuel uses. Probably the largest single use of this kind is in blast furnaces for the manufacture of charcoal iron. Many wood-distillation plants are built in connection with blast furnaces, and their entire output of charcoal is used for this purpose. It is also used largely as a special domestic fuel, and considerable quantities are still employed in the manufacture of black powder. Charcoal has also a large number of miscellaneous uses, such as in stock and poultry foods, in case-hardening compounds, and as a deodorizer and insulator.

*In charge Section of Derived Products, Forest Products Laboratory, U. S. Forest Service, Madison, Wis.

¹The United States Tariff Commission report dated 1921 shows that about 1,800,000 gal. of methanol was exported for Austria-Hungary in 1913. Most of the crude products were manufactured in what is now Czecho-Slovakia.

Acetic Acid.—Acetic acid has a wide use in the chemical industry in the preparation of various inorganic acetates such as lead, copper, and sodium acetates, and in the preparation of white-lead pigment. It is used widely in the organic chemical industry, especially in the preparation of cellulose acetate for films, lacquers, plastics and artificial silk; and in the preparation of various organic acetates, such as methyl, ethyl and amyl acetates which are used as solvents. It enters in the manufacture of various synthetic organic chemicals, even though the acetyl group may not appear in the final product. It has also several miscellaneous uses, such as in textile plants in the dyeing process and on rubber plantations for coagulating the latex.

Acetone.—Acetone is used largely as a solvent, and for certain purposes of this kind it seems to be almost indispensable. This is especially the case with certain cellulose acetate films and lacquers, which require a large proportion of acetone in the solvent for obtaining the best results. The standard high-explosive used by the British—cordite—requires the use of acetone as a solvent in its manufacture. Large quantities of acetone have also been used as a solvent for acetylene in portable lighting and welding outfits.

Methanol.—Methanol has a large number of uses for which there seems to be no substitute possible. Formerly the largest use of methanol in this country was as a solvent in the manufacture of varnishes and lacquers,

is also the base used in the rapidly increasing production of synthetic resins, such as Bakelite and Redmanol. Methanol is now used in the preparation of certain dyes which require the presence of the methyl group. Methyl acetate and methyl salicylate, or artificial oil of wintergreen, and other similar methyl esters require methanol in their production.

Methyl Acetone.—Methyl acetone, which is a mixture of methanol, acetone, methyl acetate and other impurities in small quantities, is obtained during the refining of methanol. This material naturally varies in composition as produced at different refining plants, but it has the same general uses in all cases—namely, as a solvent. It has solvent properties very similar to acetone and in general superior to those of pure methanol. Its special use, however, is in the denaturing of ethyl alcohol.

Wood Tar.—Wood tar has not yet become an important product of wood distillation, although there has been considerable development along this line within the last few years. Flotation oils, solvent oils, heavy tar oils for paints, stains, preservatives and insulating pitch are some of the important products obtained from wood tar. One important product for which wood tar is the only raw material is the medicinal beechwood creosote which has been manufactured to a considerable extent in this country since 1915.

PERIODS IN THE HISTORY OF THE HARDWOOD DISTILLATION INDUSTRY

There are several periods which stand out distinctly in the development of the hardwood distillation industry, as determined by the change in the demand for certain products. For a long time the industry was given an indirect subsidy by the Government in the form of a tax placed on ethyl alcohol for industrial purposes. This made it possible for methanol to be used and sold at a price much higher than the cost of manufacture of ethyl alcohol. It was during this period that the great use of methanol as a solvent was developed in the manufacture of spirit varnishes, in the hat-making industry and in many other places where its solvent action made it a good substitute for ethyl alcohol.

In 1906 the denatured-alcohol legislation was passed making it possible to use ethyl alcohol for industrial purposes without paying the excise tax. This put methanol in direct competition with ethyl alcohol in cases where solvent action only was required, and the market price of the product immediately dropped to about the same level as that of grain alcohol. Conditions in the hardwood distillation industry were very unfavorable for some time; but slightly increased prices for charcoal and acetate of lime helped the situation, and there continued to be a fair demand for methanol, although at a very reduced price. This condition continued until about 1915, when the demand for acetate of lime began to increase rapidly, owing to the fact that one of the main explosives used by the British Government required acetone in the process of manufacture. After the reserve stocks on hand were used up the price of acetate of lime increased very rapidly, and for some time was held at \$7 a hundredweight, when the maximum price previous to the war had been \$2.50. This demand for acetate was much greater after the entrance of this country into the war, since both acetone and acetic acid were important constituents of the airplane-wing "dope" required in large quantities by our airplane program. Methanol did not have such

BEEHIVE CHARCOAL KILN WITHOUT BYPRODUCT RECOVERY

especially those containing shellac. This use has, however, declined very rapidly of late, and only small quantities of methanol are now being used for this purpose. The uses in which methanol enters into chemical reaction with other materials have been rapidly growing.

A recently developed use of methanol as a solvent is in connection with the manufacture of moving-picture films. Its main chemical use is probably in the manufacture of formaldehyde, as it is the only raw material from which formaldehyde has been produced commercially. Formaldehyde is a standard disinfectant for general use in hospitals and sick-rooms. An even more important use for formaldehyde, however, is found in the eradication of various fungus diseases which attack seed grains. The Department of Agriculture has recommended the use of formaldehyde treatment for potatoes and for many grains, in order to prevent these diseases and increase the yields of the products. Formaldehyde

important war uses, and its price was not greatly affected. Both of these products, however, were commandeered by the Government, and the selling price was fixed. After the Government restrictions were removed the price of methanol increased, while that of acetate of lime decreased.

The change in price for acetate of lime was due to two causes. One of these was the large stocks which had been stored during the war and the other was the competition which had been developed through new processes developed during the war for the manufacture of acetic acid and acetone.

The increase in the price of methanol was due to the rapidly increasing use of this material in chemical

WOOD-DISTILLATION RETORTS

manufacture. Our newly established dye industry required considerable quantities of methanol, and the various other chemical uses for this product had increased greatly. The recent decrease in demand is difficult to explain, except by general business conditions.

Methyl acetone obtained in the refining of methanol has also shown great changes in demand. At the time it was first produced it had practically no value, because its solvent properties were not well known and both the odor and color of the product were unpleasant, but it gradually developed that this material had very unusual solvent properties, and as the color and odor were improved it was used more and more. Since the denatured alcohol bill went into effect in 1907 there has also been a slowly increasing demand for this material as a denaturant. Charcoal has also had many ups and downs following the demand for charcoal iron to a great extent, but these have not occurred in well-defined periods like the other products.

COMMERCIAL METHODS OF WOOD-DISTILLATION— RETORTS, KILNS AND OVENS

The distillation of wood has long been an industry in the form of the manufacture of charcoal without the recovery of any byproducts. This was accomplished by kilns in which the heat required for the distillation of wood was furnished by a partial combustion of the wood and its distillation products by means of a regulated draft of air through the kiln.

In this country there were two paths by which the charcoal industry progressed toward the modern wood-distillation industry in which the chemical byproducts are the chief products. One of these was the brick byproduct kiln, in which the same method of heating was continued, but the draft was regulated artificially and the products of combustion and distillation were carried through condensers and recovered. The yield of chemicals from the byproduct kilns was only about one-half of that which can be obtained by the distilla-

tion of the wood in closed vessels with heat applied from the outside. Nevertheless the byproduct kilns continued in use, particularly in northern Wisconsin and Michigan, where large quantities of charcoal were required for use in charcoal-iron furnaces. Several such plants are still in operation, but no new ones have been built recently and some of them have already been remodeled into modern oven plants.

The other path by which the wood-distillation process advanced from the kiln process to the modern methods was by way of the retort process. These retorts were cylindrical, horizontal, and about 5 ft. in diameter by 9 ft. in length. They were commonly set in furnaces with one firebox for two retorts. The wood was loaded into the retort by hand, and the hot charcoal was raked out also by hand labor. In the eastern part of the wood-distillation district these retort plants were very common, and they became the standard distillation apparatus for a time.

The modern oven for wood-distillation is at present the standard type of distillation apparatus, and all of the new plants recently built have been of this type. The ovens were developed with the main purpose of decreasing the amount of labor required, and they were very successful in this direction, since the wood was run into the ovens on cars and the charcoal removed from the retorts on the same cars without requiring any handling. From this point of view the ovens are very efficient, and the yields obtained per cord of wood are also as great as have been obtained in the other commercial forms of distilling apparatus. The ovens are about 6 ft. by 8 ft. in cross-section, and the wood on the cars does not touch the sides of the oven at any point.

The great disadvantage in the use of such ovens is that in order to bring the center of the charge up to the

LOADING BUGGIES WITH WOOD

required temperature it is necessary that the retort surface be heated to a considerably higher temperature than necessary for the distillation of the wood, which results in high depreciation on the ovens in cases where extreme care is not taken in the control of the fire.

ARTIFICIAL DRYING OF THE WOOD

The wood is commonly air-dried from twelve to eighteen months previous to distillation. This is necessary on account of the fact that green wood not only requires more fuel and a longer time to distill but the

WOOD GOING INTO DISTILLATION OVENS

liquors are also increased in amount by the moisture in the wood, with the result that during the refining process larger capacity apparatus and more fuel would be required.

There is considerable disagreement in regard to the effect of moisture in the wood in the yields of methanol and acetic acid; but it is generally considered that, even if moisture does increase the yields, it is not enough to make up for the increased costs of distillation and refining.

The cost of air-drying is considerable, since the interest on the value of eighteen months' wood supply is a large item of expense, and the handling of the wood in piling it for drying and in loading on the cars after drying is also expensive.

Within the last three or four years methods for artificially drying distillation wood have been worked out, and the same general method with modifications is in use at three plants. The woodyard for drying purposes is replaced by what are called pre-driers. These consist of brick or tile buildings, holding from one to three days' supply of wood on cars, in which the wood is heated and dried by direct contact with the flue gases from the retort stacks. The flue gases are taken from the stacks by means of fans and distributed along the hot end of the pre-drier, usually by flues underneath the cars. Some trouble was encountered at first with sparks carrying over from the flues and igniting the wood on the cars; but by using baffles for stopping the sparks and by determining the maximum safe temperature at which the gases could enter the driers this difficulty has been avoided.

As the drying of wood takes place very much more rapidly through the ends of a stick than in the direction at right angles to the grain, it was naturally found that the wood could be dried more rapidly and completely when cut into blocks instead of being left in the usual 4-ft. lengths of cordwood. At two plants the wood is cut into blocks and the blocks are loaded into cars from hoppers without being touched after sawing. At one plant the wood is still being dried in 4-ft. lengths, although the drying is then not so complete.

Short blocks of wood dumped into a car by gravity feed from a hopper will give more weight of wood in

a car than can be loaded into the same car by hand in the form of 4-ft. cordwood.

The labor required for handling the wood in the storage yards and the interest on the investment, insurance, taxes, etc., on stored wood are expenses which are entirely eliminated by the use of pre-driers. It also makes the plant more independent of weather conditions and it is possible for a new plant to start without the necessity of collecting a wood supply eighteen months before the plant is ready for operation.

RELATION BETWEEN THE COMPOSITION OF WOOD AND ITS DISTILLATION PRODUCTS

The two main constituents of wood—namely, cellulose and lignin—are very different in their yields of wood-distillation products. Cellulose when distilled by itself furnishes no methanol, but gives a comparatively high yield of acetic acid.² Lignin has not been distilled by itself, but apparently it is the only source of methanol in the original wood.

The chemical composition of wood is usually expressed in terms of certain groups of substances which have special solubilities or give certain reactions. For instance, "methoxy group," "acetic acid by hydrolysis," "alkali soluble," "water soluble" and "ether soluble" are common terms used in reporting a wood analysis.

The methoxy group is the one of most interest in wood distillation. Its determination is not a direct measure of the amounts of methanol which can be obtained by destructive distillation of the wood; but, in general, the woods which give the higher methoxy determinations give also the largest yield of methanol. The ratio between the percentage of methoxy group and percentage of methanol obtained by distillation is approximately 3 to 1, and this indicates the possibility of obtaining considerably higher yields of methanol from wood by some method of modifying the source of the distillation.

The acetic acid content as obtained by hydrolysis varies considerably with different species, but does not seem to have a direct relation to the amount of acetic acid obtained by destructive distillation. The acid obtained by hydrolysis is also less than the amount obtained by distillation and therefore does not indicate a possibility of larger yields of acid. It is possible, however, to decompose wood in such a manner as to obtain larger yields of acetic acid than have ever been obtained by destructive distillation. Thus a treatment with a large proportion of caustic soda at a temperature of about 200 deg. C. may yield as high as 15 per cent of acetic acid.³ Apparently, therefore, there is nothing in the composition of wood substances which makes it impossible to obtain considerably increased yields of both methanol and acid by some modification of the process of distilling.

The other constituents of wood, such as "water soluble," "ether soluble," etc., are not of much importance in connection with wood-distillation, since these constituents occur usually only in small amounts. In cases where the resins occur in large quantity these become important by themselves; and, as in the case of "lightwood" from longleaf pine, they form the basis of a special distillation industry.

Parts II and III will be published in subsequent issues.

Comparison of the Fusing Temperature of Coal and Coke Ash

BY HAROLD J. ROSE

A knowledge of the fusing temperature of ash has proved to be of considerable value in comparing the clinkering tendencies of various fuels. Although a large amount of reliable information has been published on the fusing temperature of ash of United States coals,

results have been obtained. All determinations were made according to the American Society for Testing Materials 1920 "Tentative Method for Determination of Fusibility of Coal Ash.":

The permissible difference allowed in duplicate determinations by the A.S.T.M. 1920 Tentative Method is as follows: Same analyst, 54 deg. F.; different analyst, 90 deg. F.

It is evident from the results obtained that the fus-

very little information is available regarding the fusing temperature of coke ashes.

A series of tests has been made to determine whether it is permissible to assume that the fusing temperature of a coke ash is identical with that of the ash of the coal from which the coke was made. The following

ing point of coal ash is not affected by the coking process, and that either coal ash or coke ash may be used for determining the fusing temperature of ash of the coal in question.

Physical Tests on Sheet Nickel Silver*

Nickel Silvers Both High and Low in Nickel Were Studied — Cold-Worked High Nickel Is Softer and Works Better and Requires a Higher Temperature for Recrystallization, After Which It Has Higher Strength and Less Elongation Without Damaging Its Cold-Working Properties

BY WILLIAM B. PRICE AND PHILIP DAVIDSON†

WE PRESENT a survey of some of the physical properties of sheet nickel silver, when subjected to cold rolling and when annealed at a variety of temperatures extending from 350 deg. C. throughout the commercial annealing range.

PREPARATION OF SPECIMENS

A number of alloys were taken from stock and analyzed. Four of these, representing low-nickel and high-nickel both with and without lead were chosen for the tests. The analyses follow:

Alloy	Per Cent Cu	Per Cent Pb	Per Cent Fe	Per Cent Ni	Per Cent Mn	Per Cent Zn
A.....	64.68	Trace	0.194	6.73	0.06	Remainder
B.....	65.82	1.27	0.227	6.17	0.06	Remainder
C.....	65.44	Trace	0.345	17.83	0.08	Remainder
D.....	65.60	1.08	0.238	17.77	0.06	Remainder

These alloys were then rolled in accordance with the regular mill practice to approximately No. 6 B. & S. gage. At this stage all of the bars (which were

then coiled) were annealed together in a mill muffle. After the annealing treatment, the bars were pickled in a 10 per cent sulphuric acid solution and cold-rolled in stages of approximately one number (B. & S.) at a time. After each stage suitable samples were set aside for physical tests. Additional samples were also chosen for tests after prescribed annealing treatment. The method of sampling is indicated below:

ROLLED SERIES	ANNEALED SERIES
No. 6, annealed in Mill	Samples were taken at the indicated stages and annealed together in the mill muffle. After pickling, they were finished on 0 050-in. gage yielding a series of specimens 2, 4, 6 and 8 numbers hard for the subsequent annealing tests.

also taken from the annealed alloys, along with the tensile specimens.

METHODS OF TESTING

Brinell tests were made with an Olsen hydraulic machine as preliminary tests on the tensile test-pieces, using pressure of 500 kg. for 30 seconds with a 10-mm.

ball. The tensile tests were made on a 50,000-lb. Olsen testing machine adjusted to take a maximum load of 5,000 lb. The yield point was considered as that load necessary to produce a permanent set of 0.001 in. in 2 in. and was obtained by measuring the elongation of the specimen during the test with a pair of dividers.

Scleroscopic hardness tests were also made on the

FIGS. 3 AND 4. PHYSICAL TESTS ON COLD-ROLLED MATERIAL

Fig. 3—Alloy C. Analysis: Copper, 65.44% ; lead, trace; iron, 0.345% ; nickel, 17.83% ; manganese, 0.08% ; zinc, remainder.
Fig. 4—Alloy D. Analysis: Copper, 65.60% ; lead, 1.08% ; iron, 0.238% ; nickel, 17.77% ; manganese, 0.06% ; zinc, remainder.

FIGS. 11 TO 16. MICROSTRUCTURE OF ROLLED STEEL SERIES, ALLOY C
Analysis: Copper, 65.44% ; lead, trace; iron, 0.345% ; nickel, 17.83% ; manganese, 0.08% ; zinc, remainder. Etched with FeCl₃ × 75.
Fig. 11—Mill anneal. Fig. 12—17.75% reduction. Fig. 13—33.95% reduction. Fig. 14—47.97% reduction. Fig. 15—66.66% reduction. Fig. 16—76.0% reduction.

FIGS. 22 TO 27. MICROSTRUCTURE OF ANNEALED SERIES, ALLOY A

Analysis: Copper, 64.68% ; lead, trace ; iron, 0.194% ; nickel, 6.73% ; manganese, 0.06% ; zinc, remainder. Etched with $\text{NH}_4\text{OH} + \text{H}_2\text{O}_2$. $\times 75$.
 Fig. 22—51.9% reduction. Fig. 23—Annealed at 350 deg. C. Fig. 24—Annealed at 425 deg. C. Fig. 25—Annealed at 575 deg. C. Fig. 26—Annealed at 650 deg. C. Fig. 27—Annealed at 835 deg. C.

FIG. 17. COMPARISON OF THE PHYSICAL PROPERTIES OF COLD-ROLLED ALLOYS A AND C

Specimens for microstructure were also taken from the ends of the test specimens before pulling. Alloys A and B were etched with $\text{NH}_4\text{OH} + \text{H}_2\text{O}_2$, while dilute acidified ferric chloride solution was used in the case of alloys C and D. All micrographs were made at a magnification of 75 diameters.

The results of the physical tests made on the rolled specimens are shown in Tables I, II, III and IV, each item representing the average of three determinations. They are represented graphically in Figs. 1, 2, 3 and 4. Representative micrographs of alloys A and C are shown in Figs. 5 to 16 inclusive.

The significance of these results may be best appreciated by an examination of the accompanying curves, Figs. 1, 2, 3 and 4. In a general way the nickel silvers with the lower nickel content are slightly harder than brass subjected to similar treatment. The nickel silvers with the higher nickel content, however, although slightly harder when in the annealed condition, do not harden as rapidly under severe cold-rolling as those

FIGS. 28 TO 33. MICROSTRUCTURE OF ANNEALED SERIES, ALLOY C

Analysis: Copper, 65.44% ; lead, trace ; iron, 0.345% ; nickel, 17.83% ; manganese, 0.08% ; zinc, remainder. Etched with FeCl_3 . $\times 75$.
 Fig. 28—52.7% reduction. Fig. 29—Annealed at 429 deg. C. Fig. 30—Annealed at 500 deg. C. Fig. 31—Annealed at 575 deg. C. Fig. 32—Annealed at 750 deg. C. Fig. 33—Annealed at 835 deg. C.

with the lower nickel content. The comparison is shown graphically in Fig. 17. In works practice, as a matter of fact, alloys with the higher nickel content are considered more amenable to cold-working operation in general than those with the lower nickel content.

The presence of about 1 per cent of lead in either alloy does not appear to affect the physical properties to any great extent.

As stated above, samples approximately 2, 4, 6 and 8 numbers (B. & S.) hard at 0.050-in. gage were obtained from each of the four alloys. Three tensile and three Erichsen specimens from each lot (making forty-eight tensile and forty-eight Erichsen specimens) were

placed on a small pan 11 x 14 in. and carefully annealed in a nichrome wound electric muffle furnace 12 in. wide x 8 in. high x 28 in. deep. The temperature was controlled by means of a platinum thermocouple used in conjunction with an Engelhardt millivoltmeter. The specimens were annealed for half-hour periods at the temperature designated plus a preheating period averaging 1 hour and 17 minutes.

The physical test results are given in Tables V to VIII inclusive. The tensile test values are shown plotted against the temperature in Figs. 18, 19, 20 and 21.

The Erichsen ductility values and the scleroscopic

FIGS. 18 AND 19. PHYSICAL TESTS TAKEN ON ANNEALED STEEL.
Fig. 18—Alloy A. Analysis: Copper, 64.68%; lead, trace; iron, 0.194%; nickel, 6.73%; manganese, 0.06%; zinc, remainder. Original samples reduced 19.55, 44.4, 51.9 and 60.5% respectively. Fig. 19—Alloy B. Analysis: Copper, 65.82%; lead, 1.27%; iron, 0.227%; nickel, 6.17%; manganese, 0.06%; zinc, remainder. Original samples reduced 18.4, 44.4, 49.75 and 59.75% respectively.

hardness values are shown in plotted form in Figs. 34, 35, 36 and 37. It is interesting to note that these curves are very similar to the tensile strength and elongation curves of the preceding Figs. 18, 19, 20 and 21; the Erichsen curve parallels the per cent elongation curve, while the scleroscopic hardness curve is similar to the tensile strength curve.

Nickel silver is similar to brass with respect to its grain characteristics excepting that grain growth is retarded by the presence of nickel. Severely worked material with the lower nickel content—alloys A and B—shows a beginning of recrystallization at 350 deg. C., which is about 50 deg. C. higher than in the case of alpha brass. In the case of the nickel silvers with the higher nickel content—alloys C and D—the first signs

of recrystallization on the hard-rolled specimens is observed at 500 deg. C.

The great differences in tensile strength, per cent elongation, etc., which are seen in the samples reduced various amounts by rolling are approximately equalized by an anneal at 425 deg. C. in the case of alloys A and B and at 575 deg. C. with alloys C and D.

EFFECT OF NICKEL ON TENSILE STRENGTH AND ELONGATION

Comparative tensile properties of the four alloys are shown in Fig. 38, which gives the annealing characteristics of material originally 4 numbers hard. It will be seen that the effect of nickel is to raise the tensile strength and lower the per cent elongation. This

TABLE VII. PHYSICAL TESTS OF ANNEALED MATERIAL.

FIG. 38. TENSILE STRENGTH AND PER CENT ELONGATION OF ANNEALED SAMPLES ALLOYS A, B, C AND D, PREVIOUSLY ROLLED 4 NUMBERS HARD

specifically higher initial strength and lower elongation are evidently not unfavorable from the cold-working standpoint, as indicated by the behavior of the metal in practice when subjected to severe reduction by rolling.

MICROSTRUCTURE

Representative micrographs of the structures of alloys A and C, originally about 6 numbers (B. & S.) hard, are shown in Figs. 22 to 33 inclusive. Referring to Fig. 23, it will be seen that alloy A shows incipient recrystallization after an anneal at 350 deg. C. At 425 deg. C. the recrystallization is complete (Fig. 24). The grains grow as the temperature rises, but it is clear that the grain size is consistently smaller than that of brass treated in a similar way. Referring to Fig. 30, it is apparent that partial recrystallization of alloy C has begun at 500 deg. C., while complete recrystallization first occurs at 575 deg. C. (Fig. 31.)

These micrographs illustrate very clearly that in order to attain a given grain size the 18 per cent nickel silver requires an annealing temperature about 100 to 150 deg. C. higher than will suffice in the case of the 7 per cent alloy.

Scovill Manufacturing Co.,
Waterbury, Conn.

Statistics of Fats and Oils, First Quarter, 1921

The factory production of fats and oils (exclusive of refined oils and derivatives) during the three-month period ended March 31, 1921, as compiled by the Bureau of the Census, was as follows: Vegetable oils, 652,230,449 lb.; fish oils, 1,037,781 lb.; animal fats, 512,557,342 lb.; and grease, 89,312,244 lb.; a total of 1,255,137,816 lb. Of the several kinds of oils and fats covered by the inquiry the greatest production, 481,778,873 lb. appears for cottonseed oil. Next in order, edible and neutral lard with 430,238,669 lb.; linseed oil with 118,786,819 lb.; tallow with 80,989,879 lb. and coconut oil with 23,062,246 lb.

Nearly all the crude vegetable oils are passed through a refining process, although some virgin oil is expressed. The production of refined oil during the three-month period was as follows: Cottonseed, 424,315,821 lb., coconut, 36,554,004 lb.; peanut, 6,523,996 lb.; soya bean, 2,289,969 lb., and corn, 11,550,768 lb.

The data for the production, consumption, imports, exports and stocks of fats and oils and for the raw materials used in the production of vegetable oils for the three-month period appear in the following statements:

Alcohol as Locomotive Fuel in Brazil

Consul C. R. Cameron, of Pernambuco, reports that there are in his district approximately 80 modern cane-sugar factories, which have about 800 miles of railway, of from 0.75 to 1 meter gage, operated at present by wood-burning locomotives. The fuel problem, however, is becoming a serious one and as a result the sugar-mill operators are turning their attention to the matter of reducing wood consumption and finding substitutes. Consequently great interest is being shown in the substitution of alcohol, which is produced in large quantities on the sugar plantations from the molasses finals. Pernambuco has recently adopted the use of alcohol to which 5 per cent gasoline has been added as an automobile fuel. The manufacturers are, therefore, naturally interested in using their own inexpensive product for their railways. The current price of alcohol is about \$0.22 per gallon, but the cost to the producer is much less.

Production of Sugar in France During the 1920-21 Season

A recent report from the office of the commercial attaché at Paris states that the total quantity of sugar delivered by the 72 factories in France from September 1, 1920, to the end of April, 1921, reached, 294,260,142 kilos, as compared with 156,377,837 kilos during the corresponding season of the previous year. The stocks remaining at the factories at the end of April amounted to 25,338,609 kilos, as compared with 6,977,050 kilos for the previous year.

The Dependence of the Lime Industry Upon Nature and Science*

An Essay Upon the Occurrence of Calcium Carbonate in Nature and Upon the Origin of the Limestone Deposits Which Form the Basis of the Lime Industry—Indebtedness of the Industry to Science—Technical and Personnel Research Problems

By ARTHUR D. LITTLE

A BUSINESS which consists essentially of quarrying and burning one of our commonest rocks and barreling and distributing the product does not at first sight seem to involve much of either science or romance. I hope to be able to convince you that it is replete with both.

In its relation to your business you think of limestone as the raw material of lime and are prone to overlook the fact that it is in reality an ore, and a most abundant one, of the metal calcium. The freshly-cut surface of the latter has a brilliant silvery luster, which upon exposure to the air is quickly dulled by the rusting or oxidation of the metal to its oxide, lime, from which through the Latin, *calx*, *calcis*, the metal takes its name. It is obviously one of the alkaline earth metals and closely resembles barium and strontium and to a lesser degree magnesium. Its specific gravity is about 1.5; it melts at about 800 deg. C. and it burns in the air with a white light to lime. It combines directly with most elements, including even nitrogen, with which it forms a nitride which, upon contact with water, evolves ammonia. A ton of pure limestone contains approximately 800 lb. of the metal, and chemically pure lime is over 70 per cent calcium. Science will ultimately find broad uses for a metal so interesting and abundant. It was discovered in 1806 by Sir Humphry Davy, who obtained an amalgam of calcium by the electrolysis of a mixture of lime and mercuric oxide. It remained a laboratory curiosity until 1900 and even as late as 1904 was quoted at £110 a pound. A year later an improved electric process brought the price to 12 shillings a kilo, or about \$1.30 a pound.

The Various Forms of Calcium Carbonate

CALCITE

Calcium carbonate, or carbonate of lime, exhibits in its various occurrences an extraordinary number of protean aspects. As calcite it is, next to quartz, the most widely distributed of minerals and notable for the beauty and remarkable variety of its crystalline forms. A number of highly important optical instruments, like the polariscope used for testing sugar, derive their usefulness from the property of double refraction possessed by calcite in the form of Iceland spar. For many years the world derived its supply of these crystals of suitable optical quality from a single quarry, a cavity in basalt in Iceland, 12 yd. long by 5 yd. wide and 10 ft. high, which yielded enormous crystals, some a yard in length.

Carbonate of lime is soluble in water containing car-

bonic acid gas, but is deposited from solution when the gas escapes. By the drip of water so charged there are built up in caves the deposits in widely fantastic shapes of stalactites and stalagmites. Carbonated springs in limestone districts may become so highly impregnated with lime as to build up terraces and basins of remarkable beauty by its subsequent deposition. Those at Mammoth Hot Springs in Yellowstone Park are doubtless familiar to many of you. Mexican onyx is another variety, and a vast deposit at Tivoli supplied much of the building stone for ancient Rome. The alabaster of the Orient was stalagmitic limestone.

LIMESTONE AND ITS ORIGIN

But ignoring such exceptional forms and speaking generally, all limestone is of organic origin, the result of the life processes of inconceivable myriads of animal organisms, and the story of its formation is at once a triumph and romance of science.

When I was a boy in Portland, Me., I spent much of my time in studying the marine life of the harbor; the starfish and anemones on the piles beneath the wharves; the sea urchins, whose projecting spines showed in section under the microscope a limestone mosaic of such wonderful symmetry and color as to make me realize for the first time how much the world contains of beauty that is hidden from most eyes; the jellyfish, big ones with sweeping tentacles and tiny ones with opalescent bands of waving cilia; the barnacles with their rhythmical projection of feathery hands in search of food. A dredge, dragged on the bottom behind my boat, brought up many treasures: among them none more wonderful than the fragile, beautifully constructed, chambered, calcareous shells of foraminifera with perforated walls. So tiny were they that a hand glass and much pains were needed for their separation, and their exquisite details of structure were revealed only under the higher powers of the microscope.

Now it is bad enough to call such tiny creatures foraminifera, but I must even ask you to remember that the commonest of them is further burdened with the more distinctive name of globigerina, for the globigerina are at least as directly concerned in the business of making lime as any of you here.

CHALK BEDS

If you rub down a piece of chalk to a thin paste with water you will find upon microscopical examination that it is composed almost entirely of the shells of foraminifera, and some common chalks are built up almost wholly of globigerina shells. Such are the chalk beds of England, which, often more than a thousand feet in thickness, extend across the island for 280 miles and at the coast line rise in those white cliffs to which

*Address delivered at the third annual convention of the National Lime Association, New York, June 16, 1921.

England owes her name of Albion. But the chalk bed stretches far beyond the coast of England, over much of France, through Denmark and Central Europe, south to Africa, and even into Central Asia. In our own country true chalk is found in Kansas, Iowa, Texas and elsewhere. As localities change, however, other types of foraminifera than globigerina become predominant in its substance. Thus the miliola, so called from its resemblance to millet seed, has built up the enormous beds of limestone in the vicinity of Paris. Certain beds of carboniferous limestone in Russia are entirely made up of the remains of another and peculiar type of foraminifera, spindle-like in shape and called because of that fusulina.

NUMMULITIC LIMESTONE

The Latin word for a coin was *nummus* and for a reason which will presently appear it gives its name to the nummulitic limestones, which extend over vast areas of North America and in a band often 1,800 miles in breadth and of enormous thickness from the Atlantic shores of Europe and Africa through western Asia to northern India and China. Of it the pyramids were builded, and from it was quarried and chiseled that memorial of antiquity, Cleopatra's Needle, which stands in Central Park.

This variety of limestone has been formed by the slow accretion of innumerable billions of the shells of foraminifera of the genus nummulites, which is characterized by shells of an extraordinary complexity of structure and a disk or coinlike form. They are remarkable also for their relatively vast size, the usual range of which is from one-half inch to an inch in diameter, though many are as large as a half-dollar and some even 4½ in. across. The significant fact is that, like the globigerina and other foraminifera, the nummulites are marine animals, and the genus is still represented, though by smaller types, in the ocean life of today.

Chalk is now forming on the ocean bottom, and there has been an unbroken continuity of chalk formation from Cretaceous times until now, while through the ages continents slowly rise.

Beneath that portion of the ocean which we call the North Atlantic lies a vast unbroken plain, which stretches from east to west for 1,700 miles. The mud and ooze brought up by dredges dragged along this plain consist almost entirely of globigerina shells or fragments of them, the tiny creatures passing their life cycle in the ocean depths where they are found. Here and elsewhere on the globe the globigerina ooze is forming chalk over 50,000,000 square miles of ocean bottom at an average depth of 2,000 ft. The overwhelming evidence is, therefore, that limestone, wherever found, is the product of aquatic life. Its common occurrence and broad distribution in the rock structure of the continents is proof that the regions of its occurrence were once beneath the sea, from which it has slowly emerged with the uplift of the land.

To those of you who think that science lacks poetry or romance or that the common things of life make no appeal to the imagination, I commend this passage from Huxley's lecture "On a Piece of Chalk":

Thus there is a writing upon the wall of cliffs at Cromer, and whoso runs may read it. It tells us, with an authority which cannot be impeached, that the ancient sea-bed of the chalk sea was raised up, and remained dry land, until it was covered with forest, stocked with the great game whose spoils have

rejoiced your geologists. How long it remained in that condition cannot be said; but "the whirligig of time brought its revenges" in those days as in these. That dry land, with the bones and teeth of generations of long-lived elephants hidden away among the gnarled roots and dry leaves of its ancient trees sank gradually to the bottom of the icy sea, which covered it with huge masses of drift and boulder clay. Sea-beasts, such as the walrus, now restricted to the extreme north, paddled about where birds had twittered among the top-most twigs of the fir-trees. How long this state of things endured we know not, but at length it came to an end. The upheaved glacial mud hardened into the soil of modern Norfolk. Forests grew once more, the wolf and the beaver replaced the reindeer and the elephant; and at length what we call the history of England dawned.

CORAL ISLANDS AND REEFS

But we do not look alone to the chalk for the origin of limestone. Its formation is still proceeding on the grand scale through the agency of the coral polyp in many of the warmer waters of the globe. Two and a half million square miles of ocean bottom is covered with coral mud and sands. The gigantic structures of the coral islands and the barrier reefs, of which one extends for a thousand miles along the Australian coast, are the work of tiny bits of animated jelly, which abstract lime from the sea water and so deposit it that it reproduces their own radiated anatomy. A similar type of limestone, which is well represented by the coral reef at Alpena, Mich., is the product of bryozoa, compound coral-like animals that are regarded as primitive mollusks. They build frondlike structures, developing ultimately into reefs and limestone.

Much of the history of the earth and much of the effort of the living organisms which it has borne is thus written into the material on which the lime industry is based. All the structural works of man fade into nothingness when compared with the results of the life activities of the minute foraminifera and the coral polyp.

PEARLS

The amazing capacity of carbonate of lime to assume forms of varied character and often of surpassing beauty is its most striking characteristic. The pearly shell of the chambered nautilus inspired Holmes to write one of the most elevating poems in the language. In the hope of securing a few grains of carbonate of lime rounded to form a pearl great companies of men shorten their lives by groping at the bottom of the sea. Curiously, the oyster forms the pearl around the dead body of an invading parasite so that, as a French writer has said, the ornament associated in all ages with beauty and riches is nothing but the brilliant sarcophagus of a worm. For myself, I prefer to derive encouragement from the fact that even so lowly a creature as the oyster can rise superior to misfortune and convert his troubles into pearls. It will interest you to know that in the Peabody Museum at Cambridge are pecks of fresh-water pearls which our Indians or their predecessors had thrown on sacrificial fires and that even today seed pearls are calcined in India and China for lime to prepare the betel nut for chewing.

MARBLE

In its metamorphosed form of marble, which, by the way, has given its name to one of the most ancient of children's games, limestone exhibits the widest possible range of texture, color and degree of purity. The marble from Mt. Pentelicus at Athens was chiseled by Greek

sculptors into forms that remain unrivalled in their classic beauty. Unhappily, much of the best Greek sculpture and architectural detail was broken up by the Turks and burned for lime. The finest works of Michael Angelo and Canova are executed in that other famous marble from Carrara. The onyx marble of Algeria was largely used in the buildings which were the glory of Carthage and of Rome. It is clouded with yellow and brown, like that found in Mexico at Tecali in large deposits. Wrought into the exquisite structure of the supremely beautiful Taj Mahal, marble gleams in the moonlight and is reflected in the pool like the fabric of an artist's dream.

A piece of limestone lying in the quarry seems a crude and simple thing, but when its history and associations are even thus partially reviewed, we find it something elaborate and complex, and rich in interest and suggestion.

Science and the Lime Industry

Similarly, the process of burning lime is at first sight a simple operation, which was successfully carried out for many centuries before the world had heard of science. It involves, nevertheless, a highly complicated series of molecular motions, changes and forces, which can be controlled to best advantage only through the agency of science. The results obtained on burning are influenced by many factors, such as the proper sizing of the limestone charge, the chemical composition of the stone, its physical structure, porosity and grain, the nature of the fuel, its heating power and sulphur content, the extent of the combustion area and the composition of the gases leaving the kiln, the volume of air admitted, the temperature of the several zones within the kiln, the flow of gases and the counter movement of the lime, the rate of cooling, the conditions of heat transference, the distribution of incoming air, and all the variations in kiln design. These are all factors which science can control. It can also produce accurate information as to the quality of the product for the aim in view.

MARKETS FOR LIME DEVELOPED BY SCIENCE

It is one thing to make good lime, but quite a different thing to find a market for it. The creation of the broad market which exists in normal times is due in large measure to scientific research. There was a time when practically the only outlet for lime was through the mortar bed. Today its use for building purposes accounts for only 28½ per cent of the lime produced for sale in the United States. About 12 per cent more goes to agriculture, the total thus accounted for being only 40 per cent. The allotment of the remaining 60 per cent is distributed among forty-one separate items, and if from them we omit the single item of calcimine, every one is available as the direct result of modern chemical research.

Let us devote a moment to a demonstration of the thesis:

The pulp and paper mills are now credited with using over 10 per cent of the domestic production of lime. They do so because Watt and Burgess developed the soda process for pulping wood, which requires lime to causticize the soda ash; because Tilghman studied the action of solutions of calcium bisulphite on wood chips and gave the world the sulphite process, by which 14,000 cords of wood are daily reduced to fiber in the sulphite pulp mills of the country. The alkali works

consume 145,000 tons of lime a year¹ because Leblanc, during the stress of the Napoleonic wars, sought and found the first cheap process for making alkali from salt and because Solvay by refined investigation developed that other method, by which salt, dissolved in strong ammonia water, is precipitated as bicarbonate of soda when the solution is charged with carbonic acid gas. In the course of the reaction the ammonia is converted into chloride, from which it is recovered by digestion with lime. Eighty-seven thousand tons goes to calcium carbide because the researches of Willson enriched the world by cheap carbide and acetylene, to which those of Franck added cyanamide. Thousands of tons of lime goes to the market as bleaching powder because Tennant solved the problem of fixing chlorine in a form convenient for transportation. Equally as the result of chemical research, lime is used in sugar factories and ammonia works, by the makers of soap and silica brick and phenol, in the gas works and at the coke oven, by makers of explosives and by the distillers of wood.

TECHNICAL PROBLEMS OF THE INDUSTRY

Fortunately for its continued progress, the lime industry is beset with many problems. In their solution lies the opportunity of the sagacious members of this association. The burning of lime is a chemical operation, and most of the problems connected therewith are fundamentally chemical problems, for the solution of which you must ultimately look to the chemist or chemical engineer. Why is it generally believed that wood is the best fuel for lime burning? Is it because its chemical composition and physical character confer upon it any singular property as a combustible? Or is it merely because it has been found to be foolproof? Now with wood rapidly becoming less and less available, how should the practice be changed to make available the much greater heating power of coal? If sulphur in coal is really seriously objectionable in its influence on operations, how may the sulphur be eliminated or its deleterious effect avoided? Doubtless we are still far from the ultimate design of kilns, but that ultimate design will not be reached until the physical chemist is taken into partnership, for it is the laws of physical chemistry that determine the effectiveness of such design.

Still more obviously must chemical research be depended upon for the better control of the quality and characteristics of the product and the elimination of those anomalies which are now the cause of irritation and complaint. Since 60 per cent of the country's production of lime is utilized for chemical purposes, it is especially important to consider more carefully the actual availability for such purposes of the lime that is produced. Of two limes it often happens, for example, that not over 80 per cent of the actual calcium oxide content of the lime as furnished is satisfactorily available within a reasonable period of time as a causticizing agent. The remainder seems to be sintered together by overheating or in combination with impurities. Of two limes apparently identical one may absorb 25 per cent more chlorine than the other. They may show radical differences when used in the causticizing plants. One may effect a quick reaction, forming a precipitate that settles rapidly, while the use of the other may be

¹This figure represents only lime sold to alkali works. In addition, about 1,500,000 tons of lime a year is produced by the alkali manufacturers for their own use.

impracticable because of the nature of the precipitate and its slow rate of settling. If used in the tanning industry for dehairing hides, one may be very active, while the other lime of identical analysis may require considerable excess to accomplish the same work. Lime from one locality may cause much trouble from irritation of the skin and the throats of workmen in the hydrate mill, whereas in other sections the dust in the air of the hydrate mill handling lime of practically identical chemical analysis has little or no such effect upon the workmen.

PLASTICITY A FUNDAMENTAL PHYSICAL PROPERTY OF LIME

In many instances it is not so much the chemical as the physical properties of the lime that determine its availability for special purposes. This is especially true as regards the proportion of lime putty formed and the plasticity or amount of sand the lime will carry when used by the building trades. Research alone can determine the fundamental cause of this variation—whether it is due to differences in size of particles, crystal structure, the presence of colloidal impurities, or what not. The problem is especially difficult to attack because of the lack of a definite and satisfactory measure of plasticity, for until we can measure a property accurately we cannot determine what tends to augment or decrease that property. Mere trial by an experienced plasterer will not yield the kind of evidence which leads to progress. It may even, I think, be questioned whether the newly developed plasticimeter of the Bureau of Standards is, after all, more than a refined and excellent practical test. Prof. Bingham of Lafayette more nearly approaches the fundamental problem when he separates plasticity into its two essential factors—mobility and yield point—and brings order out of the hazy chaos which has hitherto enveloped the word "plasticity."

FACTORS INFLUENCING THE PROGRESS IN THE LIME INDUSTRY

Research in modern industry is somewhat like a highly complicated and sensitive mechanism. It will not function properly unless care is taken in choosing the men who are to conduct it: not so much from the standpoint of their general qualifications as scholars, scientists and engineers as from the standpoint of their ability to unite into one compact body the various elements essential to constructive thinking plus its application in a concrete way in specified cases.

In the lime industry notable progress has been made in the design of kilns and in the mechanical features involving the transportation of materials from one point to another. A modern limekiln is a highly sensitive organ, which must be treated with proportionate care if results that measure its true ability are to be obtained. It is the result of careful research and stands today not as an experiment, but as a proved illustration of the value of modern research in industry. Although operating data are hard to obtain on kilns of earlier types, it is not unreasonable to suppose that a ratio equivalent to 2 lb. of lime per lb. of coal used would have been regarded as a highly efficient one. Today modern kilns properly operated often do better than 6 lb. of lime per lb. of coal over long-range periods of operation. Although the historic lime burner may have gathered his fuel from the surrounding woods at a cost which, to him, was measured by the amount of energy

personally expended, the cost to civilization in the long run has to be calculated on the basis of carbon content of the matter actually destroyed in the process. We may fairly say then that modern development in limekilns has done its bit to conserve the existing fuel supplies of the world and produce a product at a much decreased economic cost.

PERSONNEL

But it is not enough to have a highly developed instrument without adequate mentality to guide and control it. The type of lime superintendent of today is often a man who has come up through thirty years of rapidly changing conditions and is frequently disposed to regard refinements and developments with an austere eye, largely because he does not understand them. Their conception is fundamentally so different from his point of view that it is very difficult, if not impossible, for him to change his attitude of mind. The abuse of modern kilns in some instances has been so marked that one of the most prominent individuals in the lime industry today states emphatically that he prefers engineers who have never seen a lime plant in operation for technical superintendents to individuals who have had long experience in handling the older types of kilns. Criticism of this sort is an accusation against the balanced and co-ordinated development of research and indicates that the tool is more efficient than the operator.

The problems of research in its broadest sense include this problem of operating personnel, for the true significance of modern development is often poorly understood on account of the weakness of this link in the chain. One way in which every one can help, and particularly those who have been instrumental in bringing science into the lime industry, is by aiding the modern kiln to get a square deal in operation. The place for Orsat apparatus and pyrometer is not in the storeroom, but near the kiln stack, and until chemical control is intelligently used throughout a large portion of the industry much good money, that might be saved and available as profits, will continue to go up in smoke and be a loss.

France's Foreign Trade in the First Four Months of 1921

The April figures of the foreign trade of France are as follows:

	First 4 Months		Difference Francs
	1920 Francs	1921 Francs	
Imports:			
Foodstuffs.....	2,739,651,000	1,598,000,000	—1,141,651,000
Raw materials.....	5,199,976,000	3,559,000,000	—1,640,976,000
Manufactured goods.....	2,714,930,000	1,961,000,000	—753,930,000
Total.....	10,654,557,000	7,118,000,000	—3,536,557,000
Exports:			
Foodstuffs.....	474,522,000	700,000,000	+ 225,478,000
Raw materials.....	1,237,971,000	1,762,000,000	+ 524,029,000
Manufactured goods.....	2,861,362,000	4,520,000,000	+ 1,658,638,000
Postal parcels.....	197,041,000	418,000,000	+ 220,959,000
Total.....	4,770,896,000	7,400,000,000	+ 2,629,104,000

The trade balance is:

First four months 1920: Adverse—5,883,661,000 f.
First four months 1921: Favorable—282,000,000 f.

In connection with the above figures, it is noteworthy that the favorable trade balance of 129,000,000 f. which France accumulated in the first three months of the current year has been increased to 282,000,000 f. in the month of April and that a total adverse trade balance of 5,883,661,000 f. (1920) has been changed into a favorable trade balance of 282,000,000 f. (1921).

Determining Factors for the Life of a Pneumatic Tire*

BY WILLIAM G. NELSON

THERE are five very important and very decisive factors for determining the life of a pneumatic tire. Each has a direct bearing upon the other and a weakness in any one will prove a deathblow to the ultimate mileage which a tire is supposed to give. These five factors are: Rubber and compounding materials, fabric, construction, vulcanization and usage.

RUBBER AND COMPOUNDING MATERIALS USED FOR TIRES

The rubber and compounding materials are comprised of rubber, fillers, softeners, accelerators and vulcanizing agents. A mixture of rubber, sulphur and other materials is called a compound. There are various kinds of compounds used in a tire, as tread, carcass friction and skim coat, breaker friction and skim coat, and side wall. The tread must have good wearing qualities, good appearance and co-ordination with the carcass. By this last phrase is meant the ability to adhere properly to the remainder of the tire. Good wearing qualities are obtained by properly compounding suitable materials and curing agents with high-grade wild or plantation rubber. The most finely divided fillers, such as zinc oxide, gas- and lamp-black and similar mineral fillers, are extensively used due to their microscopical fineness, which gives high tensile strength, good stretch and resistance to abrasion, cutting and aging. Friction and skim coat stocks are so compounded as to give good adhesion to the fabric and a cushioning effect between the plies of fabric. These stocks are composed almost entirely of rubber, softeners, sulphur and accelerators. The vulcanizing agent, which is sulphur, and accelerators are, excepting the rubber, the most important parts of a compound. An accelerator is a material which accelerates the chemical combination of the sulphur with the rubber; since their action is so erratic in mixing, calendering and vulcanizing, only experienced men should undertake the handling of these agents. The side wall must have good appearance, as it holds one of the most conspicuous places on the tire. It is used for the protection of the fabric against chafing and moisture. Since it is continually exposed to atmospheric conditions it must have good aging qualities rather than high tensile strength or long stretch.

All compounds that come in contact with another must have good adhesion after vulcanization. The factors that bear upon this condition are: Type of rubbers selected; kind and amount of fillers, sulphur and accelerators; mixing and calendering of the compound; building of the tire, and finally the degree of vulcanization.

FABRIC

Fabric is the foundation upon which the tire is built. It is used to give stability and strength. There are two well-known classes of tires: the square-woven fabric and the cord fabric. In the square-woven fabric tire the threads in each ply run in both directions, alternating over and under as in a piece of ordinary cloth. In the cord fabric tire the threads or cords in each ply run parallel with the exception of a few

small cross threads, used simply to hold the cords in place while they are being impregnated with the rubber compound. The life of a tire would be greatly increased if internal friction could be eliminated. The internal friction caused by intermittent distortion of the tire in use is the result of the friction of the threads upon one another and the strains and stresses set up in the rubber compound. Naturally the fabric which gives the least amount of internal friction will accordingly give the longest life to the tire. Since square-woven fabric cannot be thoroughly impregnated with rubber compound the places where threads cross will be left bare and at these points flexing will cause a sawing action and the generating of frictional heat.

INFLUENCE OF HEAT ON THE LIFE OF TIRES

It has been demonstrated very clearly by experiment that when the temperature resulting from mechanical action reaches 230 deg. F. vulcanized rubber ceases to function as an adhesive compound, crumbles into minute particles which fail to resume their original condition, causing the compound to lose its function in the tire. This causes separation, weakness, and finally a blow out.

It may be interesting to know that 265 deg. F. is not an uncommon temperature reached in a tire when driven at high speed over the road; this is particularly true of large truck tires. In the case of cord fabric each thread is imbedded in the rubber compound and the internal friction is reduced to a minimum. The ideal condition would be to have each cotton fiber of the thread imbedded in rubber, but of course this is not practical and on account of weaving difficulties has not been accomplished.

CORD VS. SQUARE-WOVEN FABRIC

Since cord fabric comes closer to the ideal condition, the time is not far distant when it will entirely supplant square-woven fabric in the carcass of the tire. A step in this direction will be made when the cost of producing cord tires is sufficiently reduced to successfully compete with the square-woven tire. A brief summary of the advantages derived from the use of cord tires would include easier riding, due to greater resiliency; saving of gasoline and oil; saving of machinery, and more miles per dollar.

Fabric is also used in the breaker and chafing strips. The breaker fabric is covered with a rubber compound that will act as a binder between the soft-cushion stock and the stiff-tread stock. The breaker fabric is used to give stability to this compound and therefore to decrease the separation between the tread compound and the cushion. The chafing strips are used for protection and reinforcement.

MIXING AND CALENDERING

At this point something should be said about the mixing of the rubber and ingredients, and the calendering or application of the compound to the fabric. There are so many factors that enter into the mixing that they can be only briefly described here. Breaking down of the rubber by mechanical action changes it from a tough, hard state to a tacky, plastic condition. This influences the impregnation of the fabric, tackiness, blooming and other physical qualities, and also the vulcanization. The thoroughness of incorporation of the compounding elements has an influence upon uniform vulcanization and wearing conditions. In

*Read before the American Institute of Chemical Engineers, Detroit, June 23, 1921.

order to eliminate to the highest degree the variable conditions inherent to milling, calendering, building operations and vulcanizing it is necessary to have every process standardized and a rigid inspection to hold to a minimum the factor of the human element. Therefore all reputable manufacturers analyze thoroughly all compounding materials and rigidly inspect all fabric before these elements enter into the tire and also carefully control the degree of vulcanization in the finished product.

TIRE CONSTRUCTION

Tire construction is an art in itself. It is like the building of a machine and just as much care must be used in designing a tire as is used in designing a finely adjusted machine. As nearly every tire is built on an iron core and is vulcanized in a mold the space occupied by the tire is constant and is filled with a unit composed of many variables. Therefore when the fabric is frictioned and skim coated it is held to a gage of a maximum or minimum variation of 0.002 or 0.003 in. Likewise all other parts as top cushion, breaker, tread, bead and side wall are held to a maximum or minimum gage. The proportion of the fabric to the rubber compound must be properly balanced. The addition of an extra ply or the increase of the thickness of rubber compound may destroy this balance and materially weaken instead of strengthen the tire. It has been demonstrated many times by actual service tests that the correct distribution of rubber compound in the tire will increase its life several thousand miles; or the changing of the sulphur one-half of one per cent in a single compound will cause an equal variation in the mileage. There are many faults in a finished tire that can be attributed to improper construction, as excessive overflow, wrinkling of breaker and plies, incompletely filled molds, and weakness in the beads. These are usually remedied by changing the construction but in some instances the proper results can be obtained by changing the compound, the process of vulcanizing, or redesigning the equipment.

VULCANIZATION

There is probably no phase of tire manufacture that receives more attention than the vulcanization of the tire, and still there is no phase that is more problematical. The proper degree of vulcanization is an empirical condition existing in the various components of a tire which is determined by results obtained by road tests. Either an under-vulcanized or an over-vulcanized tire will give low mileage; even if a single part, such as cushion, breaker or tread compound, is over- or under-vulcanized, the entire tire will give poor results.

The controlling factors in a compound to obtain this empirical state are the sulphur, accelerators, rubbers, milling and calendering, time and temperature of the cure. Any one of these conditions will materially affect the state of vulcanization. The proper manipulation of these variables is a chemist's job and requires great care, thought and experience. It is absolutely essential for the chemist to have a laboratory fully equipped to make comparative physical and chemical analyses, to develop new compounds and try out new compounding ingredients. Various types of rubbers made by different methods of coagulating, washing and drying have different vulcanizing ranges and optimum cures—that is, the state of maximum efficiency when

vulcanized—therefore great care must be exercised in their selection for a compound.

Furthermore the optimum cures of all compounds must be so adjusted that in the finished product every component of the tire has simultaneously reached its maximum efficiency. Excessive milling causes the compound to vulcanize more slowly but more uniformly; decreases the tensile strength, and increases the stretch. These actions can be explained by the breaking down of the rubber molecule into its polymeric stages, each stage having its own particular range and optimum cure with its corresponding tensile and stretch. The slower a compound is vulcanized to its optimum cure the better resistance to aging it will have; therefore low vulcanizing temperature and long time is preferable for quality of product, but owing to the demands of quantity production higher temperatures and shorter times are resorted to. The scientific explanation of the effect of time, temperature and mechanical action upon quality of product is a problem of research and it is high time that some of these problems were given proper investigation by the scientific men of today.

USAGE

If the tire is neglected and abused while in service, all the care used in testing and selecting the rubbers and the compounding materials, analyzing the fabrics, standardizing the operations and maintaining an experienced organization in order to make the most uniform and perfect product will be of no avail. A pneumatic tire is designed and built to contain air or an inert gas under pressure, and there are no recommendable substitutes for it on the market today. The greatest danger that befalls a tire in service is under-inflation. Proper inflation is to the life of a pneumatic tire what proper food is to the life of a living being.

CAUSES FOR PREMATURE FAILURES OF TIRES

Eighty per cent of the failures in tires can be traced to under-inflation. Briefly the results of under-inflation are early separation in all parts of the tire, rim cutting, abnormal development of frictional heat, greater power and fuel consumption, rupturing of the fabric, splitting of tread and abnormal strain throughout the tire. The Society of Automotive Engineers, the Tire and Rim Association and all the large manufacturers of tires have agreed upon standard pressures to be used in tires and these pressures should be adhered to religiously in order to obtain the highest mileage. Overloading is another abuse that is often imposed upon a tire which causes an early breakdown of the carcass and finally a blow out. Other causes for premature failures are: Improperly fitting rims, which cause rim cutting, thus exposing the fabric to moisture and chafing; misalignment of wheels, which causes excessive tread abrasion; running over curbs, deep ruts, stones, nails and glass, which causes breaks and cuts in the tread and carcass; sudden braking, which causes tread abrasion and separation; turning corners at high speed, which causes excessive strains on the fabric and later a rupture; overheating, which causes separation, and sun exposure, which causes checking.

The ultimate desire of every motorist is to obtain the most miles per dollar per tire with the advantages of riding on a cushion of air, and the only way for him to obtain his desire and retain these advantages is to use common sense in the use and care of the pneumatic tire.

Artificial Seasoning of Steels

Review of Available Data on Length Changes and Spontaneous Generation of Heat in Hardened Steels, Together With Results of Preliminary Experiments on Artificial Seasoning by Different Methods of Several Types of Steels Used for Making Limit Gages

BY H. J. FRENCH, MET. E.

THE fact that steels, under certain conditions of work and thermal treatments, undergo changes with time at ordinary atmospheric temperatures has long been known or suspected, and it has also been definitely established that these changes can be hastened by suitable heat-treatment or other artificial seasoning methods. Very little is known, however, regarding the nature of such changes, and there are relatively few publications available which deal with this question.

So-called tempering of hardened steels in hot water (aging) has long been used. While the discovery of the fact that hardening is effected by quenching from 100 deg. C. is credited to Langley and Metcalf¹ (1892), Hetzel² calls attention to earlier experimental work carried out along similar lines by H. Carron in 1872-73.

Schottky³ has noted spontaneous generation of heat in hardened carbon steels when tempered at 100 deg. C., the magnitude of this effect apparently depending upon the carbon content and quenching temperature as well as on other factors.

BRUSH'S WORK ON HEAT GENERATION

Brush⁴ has also shown that high-carbon tool-steel and chromium-tungsten "high-speed" steel spontaneously generate heat in appreciable quantity for at least several weeks after water-quenching from a high temperature and that the rate of generation steadily diminishes with time. Samples of hardened carbon tool-steel likewise shrank progressively when tempered to "straw color," to "light blue" and finally annealed, while after hardening, certain samples gave evidence of spontaneous shrinkage for many days in measurable amount. The behavior of these latter specimens was similar to that of the former in the gradual decrease in magnitude of the observed effect, which suggested a relationship between the two phenomena. Contraction was not considered the prime cause of the spontaneous heat generation, because calculations showed it to be inadequate in amount.

In more recent experiments carried out by Brush and Hadfield⁵ specimens of a nickel-chromium steel behaved similarly when quenched from a temperature just above that of decalescence. The magnitude of the observed heat-effect was increased by a repeated treatment and persisted even when the specimen was

heated for a third time and allowed to cool very slowly to a temperature where complete recovery of magnetic susceptibility was attained before quenching. Because of this anomaly further investigation by Brush, Hadfield and Main⁶ was undertaken and some interesting facts were brought to light.

Attention is called to the fact that absorption of heat resulted from quenchings made at rising temperatures which generally had not previously been exceeded and that carbon tool-steel showed none of the eccentricities of the nickel-chromium steel when quenched below the hardening temperature; but when quenched above they behaved very much alike. It was also found that the rate of contraction of quenched steels followed the same law as the rate of evolution or absorption of heat which, after a short initial period, is approximately in inverse ratio to the time after quenching. It is generally considered that such contraction is due, at least in good part, to completion of the partly suppressed allotropic transformation.

JAPANESE STUDIES ON AGING

Matsushita⁷ has studied the nature of the slow contraction of hardened Krupp carbon steels and concludes that in well-hardened samples there is always a gradual contraction, whereas in imperfectly hardened steels there is a gradual elongation or an elongation associated with a subsequent contraction. It is stated that elongation results from the imperfect A₁ transformation, while contraction is ascribed to the separation of an unstable cementite from its solid solution (martensite) which does not affect the hardness. Complete separation of the first unstable carbide at room temperature requires several months or longer, while the same separation follows within two hours by heating the steel to 100 deg. C. The author also reports that the elongation or contraction of hardened steel is always accompanied by heat evolution.

Low elongation and reduction of area values have been noted by Reinhardt and Cutler⁸ in tensile tests made immediately after heat-treatment and machining of test-bars taken from 5½-in. square steel billets containing 0.49 to 0.55 per cent carbon. Aging at room temperatures for twelve to twenty-four hours sometimes increased ductility more than 100 per cent, whereas similar beneficial effects were obtained in very much shorter time by heating to 120 deg. C. (248 deg. F.). Evidence is presented that complete restoration of

ductility, which required about sixteen days at room temperatures, could be obtained at 120 deg. C. in twenty-five hours.

Honda and S. Saito⁹ have recently studied the effects of two artificial seasoning treatments on the properties of K. S. magnet steel of the following composition:

	Per Cent
Carbon.....	0.40—0.80
Cobalt.....	30.0—40.0
Tungsten.....	5.0—9.0
Chromium.....	1.5—3.0

Residual magnetism was not appreciably diminished by prolonged heating for 10-hour intervals at 100 deg. C. (212 deg. F.), while mechanical aging, carried out by dropping a bar 850 times on a concrete floor from a height of 1 m., decreased the magnetization by 6 per cent of its initial value.

NATURE OF SPONTANEOUS CHANGES

Undoubtedly the spontaneous evolution of heat, dimensional changes and other observed effects such as have been described above are directly associated with the initial stresses and suppression of the transformations resulting from rapid cooling (quenching). As recently pointed out by Jeffries,¹⁰ the presentation of an adequate explanation of such phenomena offers extraordinary difficulties. Admittedly an atomic rearrangement takes place in hardened steels at room temperature and because of the resistance of mechanical cohesion the time factor is pronounced.

If the character of the dimensional changes (contraction or elongation) occurring in quenched steels is dependent upon the adequacy of hardening as reported by Matsushita,⁷ it would appear that for each steel there would be a critical time-temperature relationship in quenching which would at least decrease the magnitude of such changes, and investigation of this point might well be undertaken.

STABILITY OF GAGES

Dimensional changes with time are often encountered in hardened reference gages, and their magnitude and occurrence have been found to vary considerably in gages produced from the same materials under similar conditions of manufacture. In this case, where the steel is used as a standard of measurement, changes in length and planeness of the order of 0.00005 in., which ordinarily might be neglected, become of considerable importance, as do also the methods capable of hastening their completion.

During 1919, at the request of the Ordnance Department, U. S. A., a systematic investigation of the effects of seasoning of gage blocks was planned, using five steels already employed in the manufacture of gages or those which appeared to offer possibilities for such work. A large number of gages were produced and seasoned in various ways, following which changes in dimensions were noted over an extended period. While it is not possible to draw any definite general conclusions from the results obtained, it is believed that presentation of the following data will be of interest and possibly benefit those who may at some future time elect to investigate this subject, or perhaps it will bring to light existing information not yet published.

All gages used were prepared in the gage section of the Bureau of Standards, while the actual work in carrying out the various heat-treatments was performed by H. R. Yerger, formerly of the staff, who also planned the investigation in consultation with various members of the metallurgical division, gage section and optics division. C. G. Peters and assistants of the interferometry section of the last named division of the Bureau have carried out all the measurements for flatness and length of the gages as reported in this paper.

MATERIALS AND PROCEDURE

Five steels were chosen for the work on permanence as shown in Table I. They were received in the form of 1-in. hot-rolled rounds and were first annealed and then examined microscopically for excessive non-metallic inclusions and surface decarburization. As a result of this examination a few bars were discarded, while the remainder were machined and ground into rough gages. These latter were then hardened by heating in a lead bath (equipped with suitable pyrometric control) and quenched in oil. After grinding, the blocks were seasoned in various ways and the gages were then finished in accordance with the Hoke method.¹¹

The hardening treatments used for the five steels are shown in Table II. Temperatures chosen are not very different from those ranges recommended by the manufacturers, though in one case preliminary quenching experiments were also carried out to determine what would be a suitable treatment. In selecting the various seasoning treatments listed in Table III, time and temperature variations as well as relatively rapid changes between temperatures above and below that of the room

TABLE III. SEASONING TREATMENTS USED

Code Letter	Description of Treatment
A	No treatment after hardening.
B	Heated in oil 3 hr. at 100° C. (212° F.) and air-cooled.
C	Heated in oil 3 hr. at 150° C. (302° F.) and air-cooled.
D	Heated in oil 3 hr. at 200° C. (392° F.) and air-cooled.
E	10 alternate 5-minute dips in oil at 200° C. (392° F.), and water at 0 to -5° C. (32 to 23° F.)
F	80 alternate dips as for E above.
G	44 alternate dips of 3 minutes in gasoline at 35 to 20° C. (-31 to -4° F.) and 7 minutes in oil at 200° C. (392° F.).
H	Heated in oil 1 hr. at 275° C. (527° F.).
I	Heated in oil 4 hr. at 275° C. (527° F.).

were considered important. The latter class of treatments may or may not involve a change in state depending upon the hardening conditions, whereas the former is considered to decrease the resistance of mechanical cohesion.

In making tests for planeness (flatness), the usual opticians' method of testing plane surfaces was used. Length tests were made by comparing the gages with the standard precision gages at the Bureau of Standards. The standard and unknown gage were brought into close contact with a plane glass surface and the difference in length was determined from the displacement of the interference fringes occurring when a second glass plane was made to form wedge-shaped films of air over the upper surfaces of the gages, and the film illuminated by monochromatic light at nearly perpendicular incidence. This method for testing gages is described by Peters and Boyd.¹²

IMPORTANCE OF EARLY OBSERVATIONS

A summary of the results of these measurements over an extended period, together with records of Shore scleroscope hardness and intervals between date of hardening, first and last measurements, is given in Tables IV and V for each of the five steels under considera-

¹²C. G. Peters and H. S. Boyd, "The Calibration and Dimensional Changes of Precision Gage Blocks," *Am. Mach.*, Sept. 30 and Oct. 7, 1920.

tion. It would have been desirable to have the first measurement made on each gage on the day of seasoning, which in turn might have been carried out after a definite number of days from the day of hardening. However, this was not found possible on account of the number of operations and length of time required in finishing the blocks and because of the large number of measurements for length and planeness which would of necessity have to be made on any given day. A schedule approximating this procedure as closely as possible was therefore adhered to. Though others are perhaps not in agreement with this, the writer is of the opinion that under these conditions a very important period for studying permanence (the time immediately following the hardening and finishing of the gages) has, by force of circumstances, been neglected, assuming that the changes in any given short time interval (a few days

* Negative signs before length changes refer to decrease; all other figures to an increase.

NOTE.—The 2-in. gages DB3 and DB4, subjected to treatment A, which showed no change in surface up to the time of the fifth measurements, became so badly deformed thereafter that no further measurements could be made, as detailed in the text. Attention is drawn to the fact that blocks of steel ST, DB and DR are in general considerably softer than those usually employed in production of gages. Blocks of steel HC and K are nearer the low limit of hardness generally used.

or weeks) are within the limits of experimental error of measurement. That this assumption may be in error is indicated by the behavior of gages DB3 and DB4, which received no artificial seasoning treatments (treatment A Steel DB of Table IV). These gages, which up to the time of their fifth measurements had shown no change in surface, became so badly deformed during the period between their fifth and sixth measurements that they could not be made to adhere to the glass plate at the later date. It was found that the surfaces had become cup-shaped, the inner half being fairly plane, but sloping irregularly upward to the edges, the depth of the cup-shaped figure being from 0.0001 to 0.0002 in. for DB4 and from 0.0002 to 0.0005 in. for DB3.

The work of earlier investigators as briefly discussed in the introduction further supports the writer's contention that early changes are more rapid than those occurring at a later date.

CONCLUSIONS

Based on total change from first to last measurements, the following conclusions may be drawn:

(a) The short gages ($\frac{1}{2}$ in.) showed no appreciable changes in length with or without artificial seasoning over a period of approximately seven months (first measurement one to two weeks after hardening). No appreciable changes in planeness occurred in the long gages (2 in.) with the exception of the two unseasoned blocks DB3 and DB4 mentioned above.

(b) Longer gages than those used (2 in.) would be more desirable for studying length changes with time, because of the extremely small variations actually occurring. About 6 to 8 in. is recommended.

(c) Variation in behavior of duplicate gages is confirmed by the K steel blocks subjected to no artificial seasoning treatment. One of these blocks showed no dimensional changes in 217 days between first and last measurements, while a duplicate decreased 0.00018 in. in the same period. Likewise duplicate artificially seasoned gages show differences as illustrated by steel ST, treatment D, Table IV.

(d) Except in the case of the plain carbon steel (DR) the changes in planeness are not appreciable.

(e) Gages produced from steels ST, DR and DB are softer than reference blocks ordinarily used. The latter are kept between about 90 to 100 Shore hardness. From this standpoint, steel ST is unsatisfactory, as it is not possible with ordinary treatment to maintain the hardness within the limits described. A higher-carbon alloy of this type would be more desirable, with possibly a decrease in chromium content so as not to impair its stain resistance and at the same time reduce production costs.

(f) The plain-carbon steel DR (containing 1.18 per cent carbon) appears to be the least desirable from the standpoint of permanence, showing in the main the greatest changes in length and planeness during a period approximating seven months from first to last measurements. Probably the most desirable are steels HC and K subjected to definite seasoning treatments, the former being the steel generally used in production of reference gages at the Bureau of Standards and closely agreeing with the composition of Johanssen blocks.

(g) None of the seasoning treatments applied has been effective in preventing dimensional changes (within the limits of measurement) in all five steels. Also all seasoning treatments applied appear to effect permanence in Steel DB (containing 1.18 per cent C, 2.20 per

cent Mn and 18.10 per cent Cr). Treatments H and I, however, have decreased the hardness.

RECOMMENDED HEAT-TREATMENT

(h) Seasoning treatments E and F, consisting respectively of ten and eighty alternate 5-minute dips in oil at 200 deg. C. (392 deg. F.) and ice water at 0 to -5 deg. C. (32 to 23 deg. F.) are the most generally effective treatments tried for obtaining permanence. Probably less than eighty would in many instances suffice to bring the steel in a state of rest under conditions of treatment and manufacture as previously outlined.

Measurements made at intervals of approximately one and two weeks, one, two, four and seven months after initial readings of length and planeness do not give very much information regarding the progress of the changes taking place. Unsuitable steels exhibiting the greatest instability in either length or planeness appear to increase progressively in error with time. In many cases of more suitable steels possessing great constancy these changes seem to occur in the intervals immediately following the first measurement, the gages thereafter remaining constant. However, no very definite statements may be made in this respect.

SHRINKAGE IN STEEL

In a majority of the blocks examined showing dimensional changes there is an elongation, but in the case of steel K shrinkage only is observed. This is unusual, as the changes observed in hardened blocks are usually of the latter type—i.e., decrease in length. Four unsea-

soned gages produced from this latter material (containing 0.87 per cent C, 1.10 per cent Mn, 0.46 per cent Cr, 0.43 per cent W, 0.12 per cent V) will illustrate progressive shrinkage in hardened steel over an extended period. (Table VI.)

No satisfactory explanation for such difference in behavior can be given at this time, but it is of interest to note that microscopic examination indicates more complete hardening of the K steel blocks (martensite-troostite throughout) than is obtained by oil-quenching the carbon-steel gages (DR) which show a less uniform structure consisting of troostite and sorbite at the surface and sorbite in the interior, indicating but local and partial suppression of the transformations and less complete hardening. In view of this fact the work of Matsushita¹ and his conclusions that the type of dimensional change (elongation or shrinkage) is related to the character of hardening becomes of particular interest.

Legal Notes

BY WELLINGTON GUSTIN

Churchward Patents Held Not Invention—Prior Art and History of Vanadium Alloys

In holding the Churchward patents, 845,756, claim 1, and 868,327, claims 1 and 3, each for an alloy of steel, void for want of invention, the United States Circuit Court of Appeals, Third Circuit, discussed the history and growth of the metallurgical art in alloy steel. (Bethlehem Steel Co. vs. Churchward International Steel Co., 268 Federal, 361.) James Churchward, the inventor, secured the patents in 1907 and assigned them to the Churchward International Steel Co., wherein the Carnegie Steel Co. intervened. The U. S. District Court sustained the claims in the patents and found them to be infringed, whereupon the Bethlehem Steel Co. appealed. The Court of Appeals reversed the District Court.

It was said that in the manufacture of steel from alloys in countless combinations and proportions it became known that small quantities of alloying metals and small differences in their proportions frequently make considerable difference in the properties of the resultant steel. Investigation of the metal vanadium, discovered in 1830 in a specimen of iron obtained from ores at Taberg, Sweden, was continued with its widening production from the slags of the Taberg blast furnaces and from mines later found in Scotland and Mexico.

INTRODUCTION OF VANADIUM IN AN ALLOY

Since about 1890 to 1900, when alloy steels became established, the use of vanadium as an alloying metal has grown apace with the discovery and development of its properties. It was discovered that vanadium lay between carbon and chromium in the properties it impresses upon steel and that small amounts, ranging from 0.10 per cent to 0.50 per cent, increase substantially the tenacity, elastic limit, tensile strength and the fatigue resistance of the metal, and also its malleability and hardness after tempering. Hence its adaptability in alloy steels where, as in armor plates, especially hard surfaces are required, and where, as in automobile and locomotive parts, shock and vibration are constant and metal fatigue inevitable.

So the use of vanadium as an alloying ingredient in alloy steel increased in the metallurgical art as these properties were revealed. Before vanadium thus came into use the art contained a variety of alloy steels named and known by the essential ingredients composing them. Aside from carbon and manganese steels, whose controlling ingredients were present by nature, or when desired were increased by additions, the patent records and the literature of the art showed nickel steels, chrome steels, nickel-chrome and chrome-nickel steels, whose characteristics were those inherent in their dominant alloying materials. Later vanadium was added to these, and in consequence there came into the art vanadium-carbon steels, vanadium-nickel steels, chrome-vanadium steels, "whose distinctive characteristics reflected the dominance of their alloying elements."

This was the state of the art, as was said, when Churchward entered it with his two patents. It was claimed that these inventions showed for the first time, in addition to the natural alloying elements of carbon and manganese, the three added elements of nickel, chromium and vanadium, thus establishing, as it was contended, the first vanadium-nickel-chrome alloy steel.

Both of the patents in suit relate to alloy steels as distinguished from carbon steels or normal steels. Both claim an alloy containing, in different proportions, the same alloying metals of steel (with varying carbon content), nickel, chromium, manganese and vanadium. In neither patent is it clear whether the invention disclosed is in the alloying metals or in their proportions or in both. So also in neither is it claimed that the resultant product contains or has in higher development the properties known to characterize the constituent alloying ingredients either separately or in combination.

The only new property, says the court, claimed for the alloy of the patent is found in the following language:

"It is believed that the alloying elements named react on each other to produce chemical and molecular changes of such a nature that the tungsten, chromium and manganese are permitted to harden the steel, while the *vanadium removes or prevents brittleness and imparts toughness without softening the alloy*. . . . In cases where the product is to have extreme toughness and hardness the tungsten may be omitted"—as it is from the claim in suit.

The specification of the second patent differs little from the first. The same theory of chemical reaction and molecular change described in the first patent is repeated in the second, differing from the first only in addition of nickel to the element of vanadium in effecting removal or prevention of brittleness without softening the alloy. On comparison it is seen that the alloying metals are the same in both patents, the proportions of those in the second patent covering the proportions of those in the first. The proportion of each ingredient in each patent begins at the same minimum, and in the second patent the proportion of each ingredient comes up to that of the first patent and passes on to a higher maximum, producing, as the only difference, as the court saw, a range wider in the second than in the first, without any claimed difference in results, properties or performance of the two alloys.

While the patents are *prima facie* evidence that the alloys constitute invention, still such is open to attack should they lack new and advantageous properties over the prior art, said the court. And so the defendant attacked the *prima facie* case.

COURT'S DICTUM ON PATENTABLE NOVELTY

The court said patentable novelty may reside either in the elements of alloys or in the proportion of the elements. If novelty of elements is claimed on the first patent, that patent falls when it is proved that before Churchward vanadium was used with chromium, nickel, manganese and carbon in alloy steels. If novelty of elements is claimed in the second, that patent likewise falls as the first. Therefore novelty in the invention must be found in the proportion of the elements. On this issue the defendant showed that in endeavoring to determine experimentally the value of vanadium in nickel-chrome-manganese steel alloys it had used the elements of the patent alloys in substantially the same

proportions specified by the patents before Churchward's alleged inventions. However, the court said this was not taken as conclusive of anticipation, for it was possible that the defendant, in employing the same elements in the same proportions, may not, because of difference in heat-treatment, have obtained the alloys of the patents. (Pittsburg Steel & Iron Co. vs. Seaman-Sheeth Co., 248 Fed., 705.)

But novelty of proportions in the sense of the patent law involves something more than figuring out proportions differing from any that were known before. It involves new results from new proportions, developing a new metal, or, it may be, an old metal with new characteristics of structure or performance, embracing entirely new, or at least substantially enhanced, qualities of utility. (Miami Copper Co. vs. Minerals Separation, Ltd., 244 Fed., 752.) To prove that the alloys of the patents in the proportions specified lack patentable novelty the defendant produced evidence, which in the absence of contradiction, the court said, must be accepted as conclusive.

DEFENDANT'S EVIDENCE UNCONTRADICTED

On the issue whether the alloys of the patent contain advantageous properties over alloys of the prior art made from the same elements in different proportions, or whether they contain properties different from those of the prior art, the defendant offered evidence to prove that while vanadium has a beneficial effect in carbon steels, in nickel steels and particularly in chrome steels, it has no such effect in chrome-nickel steels; that instead of producing the only new and useful property in the resultant steel claimed for it in the two patents—the removal and prevention of brittleness—vanadium increases brittleness, that it (Bethlehem Steel Co.), after using vanadium in nickel-chrome-manganese alloys within the range of the proportions of the patents, found that vanadium introduced a detrimental condition in the product and in consequence abandoned its use; that Carnegie Steel Co. (though under license of the patents and free to continue) found it troublesome to get out tonnage when adding vanadium to a nickel-chrome-manganese alloy and likewise abandoned its use; and that Midvale Steel Co. after experiments was not sufficiently encouraged to begin its use.

The plaintiff controverted none of this evidence, and the defendant's evidence was taken as truth. Neither did the plaintiff produce evidence that the alloys of the patent were novel or that they contained new elements of utility, in that they were different from or better than prior nickel-chrome-manganese-vanadium alloys either in metallurgical or physical characteristics or in performance. It rested first on the presumption of utility of the alloys arising from the fact that defendant had made such alloys. While this is valid evidence, it alone does not prove in the light of the case that the utility of the patented alloys was greater than or different from that of kindred alloys made before the patents. Vanadium was an alloying metal of the prior art and free to be used by anyone desiring to use it.

To constitute invention in the continued use of vanadium it must appear, said the court, that some new property had thereby been attained or some newly useful result had been achieved.

Again the patent owners relied on proof that Carnegie Steel Co. had paid it the substantial sum of \$275,000 in settlement of infringement litigation and for licenses

under the patents. But the court said that unless it were to substitute the opinion of the experts in metallurgical knowledge of the Carnegie Steel Co. for its own judgment, without knowing what evidence was before them but well knowing the evidence before it was not before the Carnegie experts, it must resolve the issues as the case has been made by the evidence. And this was done by finding that the evidence was against invention.

Chemical Company Obtains Reversal of Decree Under Workmen's Compensation Act in Maine

In a compensation case the Supreme Judicial Court of Maine has said that the Industrial Accident Commission, while primarily a judicial body, exercises certain judicial functions and in the exercise of these functions it acts judicially, and, while it determines finally the trustworthiness and weight of testimony, its findings must be based on evidence.

Further, it is said the findings of fact under the workmen's compensation act by the Industrial Commission cannot be disturbed by the courts in the absence of fraud, but such findings must be grounded upon evidence presented under such circumstances as to afford full opportunity for comment, explanation and refutation. (113 Atlantic, 28.)

The case involved proceedings by M. Gauthier under the act to obtain compensation for the loss of a leg in the employ of the Penobscot Chemical Fiber Co. There was an award of compensation and the chemical company appealed, resulting in the Supreme Court reversing the decree.

The Maine statute, chap. 50, sec. 21, authorizes certain medical testimony to be taken ex parte, but, says the court, such is not to be made the foundation of a decree until it is produced in evidence, so that either party may have an opportunity to explain or contradict it.

Wages in German Metal Industry

The Union of German Metal Workers is the largest trade-union in Germany and includes more than 1,600,000 members. This union has a statistical bureau which has collected statistics of wages and of cost of living in the metal industry, including in its investigation not only the members of its union but many other workers in the metal industry, so that the investigation covered a total of about 2,300,000 workers. It has published the results of its investigation in the *Metallarbeiter*, which is the organ of this powerful union.

According to the statistics of this union about 63 per cent of these workers are receiving wages which are more than 800 per cent greater than those of 1914, about 36 per cent are receiving wages from 500 to 800 per cent greater than in 1914, and the remainder are receiving wages which have not increased as much as 500 per cent since 1914. It is impossible from these statistics to arrive at an average wage increase for the whole of this group of workers.

The trade-unions estimate that the entire cost of living for a family of four has increased about 1,550 per cent since 1914, while Calwer's Bureau (a private statistical bureau), which usually makes use of official statistics, estimates that the cost of food alone for a family of four has increased about 1,470 per cent since 1914.

Quantitative Determination of Potash by the Spectrum

BY D. PAUL ROGERS

THE value of a quantitative determination depends upon three factors; time, cost and accuracy. The fundamental purpose of this experiment is to lessen the time for the determination, to reduce the cost of the chemicals and apparatus and to have a favorable degree of accuracy.

As a result of several determinations in 1918, it was found that the average time for the determination was one hour. This is a saving of time from 50 to 95 per cent over the old standard method of chloroplatinic acid method.

A very inexpensive chemical is substituted for the valuable platinum salt which is used in the "chloroplatinate method." An ounce of potassium nitrate when made into solutions is sufficient for hundreds of determinations. When water-soluble potash alone is wanted, there are no chemicals needed. Calcium carbonate and ammonium chloride are the only chemicals needed for determination of total potash. The total cost of chemicals for a determination would not exceed 5c.

Two sets of determinations were made on samples of flue dust containing potash in variable amounts. One of the samples was of a known content. The potash content of another sample was unknown. The latter sample was determined at the same time that an umpire chemist was analyzing by the "chloroplatinate method." These results checked up very reasonably.

SPECTRUM METHOD FOR POTASH

This method for determining potash is quite simple in that it measures the intensity of the potassium flame. The method that I worked out requires an accurate eye. The intensity of the potassium flame of various solutions of known content were very accurately recorded. The intensity of the unknown samples were likewise recorded and compared with those of the known potash content.

For a determination of water-soluble potash a 10-g. sample was taken and boiled in about 30 c.c. of water for about half an hour. It was then filtered and concentrated to 10 c.c. For a total potash determination a smaller portion is sintered by the J. Lawrence Smith method, using 0.5 g. of ammonium chloride and 5 g. calcium carbonate. The sintered mass is digested in water and then filtered. The strength of the solution is brought to the same concentration as the above.

A round loop was made on the end of a platinum wire by wrapping it around the lead of a pencil. The purpose of this loop is to have a uniform amount of solution on the film. Satisfactory blue spectacles were used to observe the potassium flame against a white background in a dark room.

Five solutions of potassium nitrate of different strength were made so that they should have a potash equivalent of 5, 7.5, 10.0, 12.5 and 15.0 per cent. For the 5 per cent solution 3.219 g. of the salt was dissolved in 30 c.c. water; 4.8285 g. for the 7.5 per cent; 6.438 g. for the 10.0 per cent; 8.0475 g. for the 12.5 per cent, and 9.657 g. for the 15.0 per cent solution, all in the same amount of water.

Two samples of flue dust of 10 g. each were treated with boiling water for about thirty minutes. The solutions were filtered and concentrated to 10 c.c.

The time of the duration of the potassium flame was determined by dipping the loop of the platinum wire into the solution and then into the flame. Twenty trials on each solution were completed before taking up the next solution. Then the same procedure was used on each of the samples to be analyzed. Each test showed the numbers of seconds of duration of the potassium flame. The following results were obtained:

Trial No.	5 per Cent. Seconds	7.5 per Cent. Seconds	10.0 per Cent. Seconds	12.5 per Cent. Seconds	15.0 per Cent. Seconds	Sample 1, Seconds	Sample 2, Seconds
1	3	5	4	4	5	3.5	3
2	4	4	4	4	5	3.5	3
3	5	3	3	4	5	4	3
4	3	4	4	4	4	4	4
5	2	3	4	4	5	3.5	3
6	3	3	4	3	5	3.5	3
7	3	3.5	5	3	5	4	3
8	3	3	4	4	5	4	3
9	2	3	5	4	5	3.5	3
10	3	2.5	5	5	5	4	3
11	3	3.5	4	5	5.5	4	3
12	4	3	5	4	5	3.5	3
13	2.5	2.5	3	5	5	4	3
14	2.5	4	3	5	5.5	4	3
15	3	4	4	6	4.5	4	3.5
16	2	3.5	4	5	5.5	4	3.5
17	3	3	3	5	5.5	4	3
18	2.5	4	4	6	5.5	5	3.5
19	3.5	3	3	4	5	4.5	3.5
20	3	4	4	5.5	5.5	5	3.5
Total.....	60	68.5	79	89.5	101.5	79.5	63.5
Average...	3	3.43	3.95	4.48	5.08	3.98	3.18

The average number of seconds of the various samples of solutions of potassium nitrate of known potash content are in progressive order as follows: 3 seconds, 3.5, 4.0, 4.5, 5.0, 4.0, 3.2.

The difference in the above series is only half a second. This half a second is equivalent to 2½ per cent of potash. The average of one-tenth a second will therefore be equivalent to half a per cent of potash.

Sample 1 of the unknowns produced a flame for an average of four seconds. Either calculating or looking

FIG. 1

up the value on the chart of Fig. 1, the percentage of potash in the sample is 10 per cent.

Sample 2 had a flame duration of three and two-tenths seconds. The value of potash here is 6 per cent.

Each one of the samples of the above results was run for the entire twenty trials before taking up the next one. In this way there were no contaminations to interfere with the results obtained.

A second series of determinations of samples 1 and 2 in addition to the solutions of known potash content was made. The following results were obtained:

Solutions	5%	7.5%	10.0%	12.5%	15.0%	No. 1	No. 2
Flame Av., sec.....	3	3.6	4.15	4.6	5.1	4.2	3.15
Progressive order, sec.....	3	3.5	4.0	4.5	5.0	4.2	3.1

From the chart, Fig. 1, the potash of sample 1 is 11 per cent and sample 2 is 5.75 per cent potash.

The average of these results compares accurately with analysis of the standard chloroplatinate method.

	Spectrum No. 1	Spectrum No. 2	Chloroplatinate Method
K ₂ O.....	10.00%	6.00%	No. 1
K ₂ O.....	11.00%	5.75%	No. 2
Average.....	10.50%	5.88%	10.46%
			5.90%

Harrisburg, Pa.

Laboratory Furnace for Deformation Temperature of Refractories

BY LEON R. OFFICE

FOR a good many years laboratories that have been testing high-grade refractories, as fireclay, fireclay and silica bricks, silica cements, etc., have been confronted with the problem of a suitable type of furnace that is both cheap in construction and simple of operation and one that can be depended upon day in and day out, without much loss of time for repairs.

The author has in mind such a furnace for which he claims no originality of principle, but which was developed through four years of experience in obtaining the softening and deformation temperatures of various refractories. Innovations were tried, such as: different sized chambers, various types of burners, length of burner, thickness of walls, insulation features, etc., and the type to be described seemed to work advantageously. It is not so difficult to deform pyrometric cone 32 (approx. 1,705 deg. C.) but to reach cones 34 and 35 is more troublesome.

R. T. Stull and J. M. Knoté¹ describe a small "pot" furnace of the muffle type, with a combination of up and down draft. It has been the writer's experience that while the temperature may be a trifle more uniform in the muffle, it is also one to three cones lower than in an open furnace and muffle shapes are just complicated enough as to be out of condition most of the time.

C. E. Fulton² describes a pot furnace of the "open flame" type, with one burner which gives the flame a spiral motion. This furnace was used in our laboratories for several years and was the basis of the type used at present.

The furnace consists of two parts, the furnace proper and the preheater. Fig. 1 shows the details.

The furnace proper consists of a pot 12 in. wide and 13 in. high, with a chamber 6½ in. in width and 10½ in. in depth. It was found that a deep and narrow chamber produced the best results, since it has a "stack-effect" of drawing the gases and flame upward with a swirling motion. None of the gas would burn in the center. The pedestal could be varied in height, just so it was above

FIG. 2. FURNACE AND AIR PREHEATER

the gas inlet. The "pot" containing the cones is placed on top of the pedestal. The top is one piece, 1½ in. thick, with a 2-in. inspection hole in the center. If banded with a heavy iron band, its life will be increased several hundred per cent. The furnace must also have an iron band which can be slipped over and bolted on one side.

A high-grade fireclay or a mixture of calcined bauxite and plastic fireclay can be used in making the furnace. The better the material the longer and more satisfactory will be its life.

The preheater consists of four lengths of 2-in. iron pipe, connected at the ends with U's and spaced so that the flame from the gas burners below will surround them. The air was not sent through the preheater until the furnace had attained a good red heat, as it increases the temperature too rapidly. Just as soon as air was sent through the preheater into the furnace, the temperature could not be regulated until almost a white heat was reached. With the preheater used, the air reached a temperature of 250 deg. F. at the burner.

Several types of burners on the market were tried, but proved less satisfactory than the homemade one shown in Fig. 1. The nozzle was 1½-in. heavy iron pipe, 6 in. long, connected to a reducing cross which acted as the mixer. Gas entered the mixer through ¾-in. pipes on two sides. A reducing bushing was placed in the rear end of the mixer, with six ⅛-in. holes, equally spaced. The air entered through a ¾-in. pipe, the opening of which extended just beyond the gas inlets, in order to prevent back pressure on the gas. The air, coming in at high pressure, tended to suck the gas with it and also excess outside air through the six holes in the back of the mixer. With air at 25 to 30 lb. pressure and natural gas in the Pittsburgh district under a pressure of about 2½ lb., a temperature sufficient to melt cone 35 in forty-five minutes was attained. Fig. 2 shows a picture of the apparatus.

This furnace, when made of a good refractory material, is very sturdy and can be used for fifty to sixty runs. Cracks can be instantly patched with Norton's alundum cement and, after several heats, a glaze develops on the inside surface which protects the pot from further attack by the flame.

Pittsburgh, Pa.

Biakmetal

During 1919, it was reported in *CHEMICAL & METALLURGICAL ENGINEERING* (vol. 21, p. 632), an Italian succeeded in producing a new alloy of zinc and copper, to which the name of Biakmetal was given. For this new alloy it was claimed that it possessed:

- (1) The highest known breaking point;
- (2) The highest limit of elasticity;
- (3) Perfect homogeneity;
- (4) High resistance to thermic action;
- (5) High resistance to chemical action.

It was further claimed that the new alloy had already proved especially useful in aëronautic and marine construction on account of its light weight, its unusual strength and its anti-corrosive qualities. It was stated that a company with a capital of 12,000,000 lire had been formed to engage in the manufacture of the alloy.

On the strength of these reports, one of the bureaus of the Government which was interested in securing a light metal of great strength obtained through official channels samples of Biakmetal for test. The samples submitted were too small for any tests other than chemical analysis, but this revealed that a variety of different alloys were grouped under the single trade name. Biak No. 2 was an ordinary 60:40 brass containing a little manganese. Biak No. 3 was the same with Ni instead of Mn. Biak No. 4 was a high red brass containing both Ni and Mn. Biak No. 6, was a high-aluminum: zinc: copper alloy, containing a little silicon. Biak No. 9 and No. 19 were high-zinc: aluminum: copper alloys such as have come into use in France for extruding purposes and as bearing metals.

Impact Strength of Carbon Steel

As an addendum to a paper on "Impact Tests on Cast Steel" read before the last meeting of the American Society for Testing Materials, F. C. Langenberg presented a useful table of impact strength of rolled and heat-treated steels. The results given in the table were obtained from specimens cut from bar stock approximately 1 in. in diameter, after various heat treatments. The table shows the composition of the several bars as well as the heat treatment.

- Heat-treatment was as follows:
- A — Original, as received, probably hot rolled.
 - B — Annealed just above A_{c_3} .
 - C — Hardened in water from just above A_{c_3} .
 - D — Hardened in oil from just above A_{c_3} .
 - E — Quenched in oil from just above A_{c_3} , drawn at 375 deg. C.
 - F — Quenched in oil from just above A_{c_3} , drawn at 460 deg. C.
 - G — Quenched in oil from just above A_{c_3} , drawn at 560 deg. C.
 - H — Quenched in oil from just above A_{c_3} , drawn at 650 deg. C.

Recent Developments in the German Chemical Industries

A recent report of the German dye trust states that during 1920 its gross profits amounted to 531.7 million marks. The bulk of this, according to the report, was made mainly during the first half of 1920, since there was a decided drop in business during the latter half of the year. The six works of the trust shared in the gross profits as follows:

	Marks
Badische Anilin- und Soda-Fabrik	144,246,000
Farbwerke vorm. Meister Lucius & Brüning (Hochst) ..	111,200,000
Farbenfabriken vorm. Friedr. Bayer & Co.	99,700,000
Actien-Gesellschaft für Anilin-Fabrikation	55,000,000
Griesheim-Elektron	41,000,000
Weiler-ter-Meer	21,000,000

The balance sheets of the individual companies make it appear that large reserves have been set aside and that the actual profits were in fact much higher. It must be considered, however, that notwithstanding the fact that the 1920 profits were more than five times as large as in the prosperous year of 1912, they are, when expressed in gold marks, but slightly more than one-third as large. The following figures show the returns for 1912 and 1920 when compared on a gold basis:

	Value in Gold Marks	
	1912	1920
Badische Anilin- und Soda-Fabrik	27,791,000	12,900,000
Farbwerke vorm. Meister Lucius & Brüning ..	22,973,000	7,510,000
Farbenfabriken vorm. Friedr. Bayer & Co. ...	28,746,000	6,650,000
A.-G. für Anilin-Fabrikation	9,738,000	4,070,000
Weiler-ter-Meer	3,379,000	2,790,000
Griesheim-Elektron	8,516,000	1,600,000
Total	101,173,000	35,520,000

All of the individual members of the trust have lately raised their capital stock, ostensibly for the purpose of developing the nitrogen works, although it has been somewhat of a puzzle to observe that this large amount of capital has been set aside for no other visible purpose. This puzzle has now been solved by the recent announcement that arrangements have been made to purchase the stock of the firm of Leopold Cassella & Co., which is the largest German dye manufacturer outside of the combine. The stock of the company is to be taken over by the members of the trust in proportion to their own capital stock.

The dye trust has also assumed complete control of Germany's nitrogen production. This industry was started by the Badische Anilin- und Soda-Fabrik of Ludwigshafen with the works at Oppau, to which were later added the Merseburg and Leuna works. The completion of these plants proved too much of a burden for a single company and for some time past the other members of the dye trust have been contributing necessary funds, although all of the stock was held, at least nominally, by the Badische company. This state of affairs has now been rectified by the formation of the nitrogen combine, equipped with a capital of 500,000,000 marks, held solely by the members of the dye trust. The further capital investment required for completing the works is over 2 billion marks.

RESULTS OF CHARPY TESTS ON FORGED STEELS, CHARPY VALUES IN FT.-LB

The nitrogen works are reported to be operating at full capacity with the exception of the Leuna works, which have not yet recovered from the communistic riots of last March. Their production has already made Germany practically independent of the imports of Chilean nitrate and of the large quantities of nitrogen salts formerly received from Norway, Sweden and Switzerland. The imports from Chile, which in 1913 amounted to 774,000 tons, had decreased during the first nine months of 1920 to 31,000 tons. Nitrogen salts from Norway, Sweden and Switzerland fell off from 86,000 tons to 2,500 during the same period.

The world monopoly enjoyed by the German potash industry before the war has been shattered and the industry is now going through a critical period. The competition of Alsace and the heavy freight rates have caused a considerable reduction in exports and the industry is now on the point of shaping a new business policy. It is likely that the future policy will be to export only the richest grades of the crude materials and the refined salts, such as potassium chloride and sulphate.

Due to the short-sighted policy of the Kali Syndikat, which rationed the business in hand according to the number of pits in operation, there has been a large increase in the number of mines, and during the present business depression this has naturally resulted in overproduction. The National Kali Council, which is now the supreme body in control of the industry, has therefore ordered the closing down of all works which by their results show that they cannot operate economically. As a result of the recent amalgamations and purchases the Kali Syndikat now consists of 17 individual members, comprising 175 mines, and representing nearly 80 per cent of the total output.

Synopsis of Recent Chemical & Metallurgical Literature

Subdivision in Sections of the Société de Chimie Industrielle.—At a meeting of the Société de Chimie Industrielle Paul Kestner, the president of the society, described the new subdivisions in sections which, it is expected, will contribute to a better study of the various particular chemical problems. The new sections are: Installation of plants; installation of laboratories, gas and coke; hydrocarbons, petroleum; wood distillation and derivatives; refrigerating; metallurgy and electrometallurgy; precious metals; heavy chemicals; electrochemistry; lime, cement and building material; glass ceramics and enamelled ware; general chemicals; rare earths; radioactivity; dyes; pharmaceuticals; photographic products; powders and explosives; essences, natural and synthetic perfumes; resins, paints, lacquers, varnishes and waxes; rubber and its substitutes; fatty materials, soap, candles, glycerine; cellulose, paper; plastic materials, artificial textiles; bleaching and dyeing; tinctorial and tanning extracts; tanning and allied industries; fermentation sugar, starch and allied industries; dairy industry; food industry. All these sections combined will hold only one annual general meeting.

He also stated that the Société de Chimie Industrielle will co-operate henceforth on a more active scale with the Fédération Nationale des Associations de Chimie and with the Union Internationale de la Chimie Pure et Appliquée.

The National Federation of the Chemical Associations, founded in 1919, consists of the following individual societies: Chemical Society, Society of Chemical Industry,

Association of Sugar and Distillery Chemists, Society of Expert Chemists, Society of Physical Chemistry, Society of Biological Chemistry and the Association of Textile Chemistry.

The International Union of Pure and Applied Chemistry, founded also in 1919 (see *CHEMICAL & METALLURGICAL ENGINEERING*, vol. 20, No. 11, p. 561, June 1, 1919), has now accredited members from twelve countries—namely, Belgium, Canada, Czechoslovakia, Denmark, France, Great Britain, Greece, Holland, Italy, Poland, Spain and the United States. (*La Technique Moderne*, May, 1921.)

Case-Hardening.—Some of the facts and fallacies connected with the subject of case-hardening were dealt with recently in a lecture by Dr. L. Aitchison before the Birmingham Metallurgical Society and reported in the *Ironmonger*, June 11, 1921. The purpose of case-hardening is to enable the use of a material both easy to machine and cheap to produce. The first point to be decided was whether case or core played the more important part, and on this question there was great divergence of opinion, many authorities holding that the former took precedence by reason of its being the actual working part. Referring to the essential properties of both case and core, the lecturer pointed out that "hardness" was the generally accepted term for defining the necessary quality of the case, but "toughness" was really a more suitable word, since it implied a capacity for wear without brittleness. Such toughness could be obtained by the introduction of carbon and other alloys. The core, on the other hand, should emphatically be soft to admit of easy machinability and consequent cheapness in handling; it must also be capable of assuming varying degrees of strength, with a possible range of 60,000 to 170,000 lb. per sq.in.

As to the problem of testing the durability of the treatment, though numerous methods were known, there is not a really satisfactory one available. The degree of surface hardness could be to some extent approximated by scratching with a file; but, at the same time, a steel containing about 5 per cent nickel and 0.2 per cent carbon is readily susceptible to scratching, and yet withstands wear remarkably well, so that the most useful test is microscopic examination, which reveals the nature of the crystalline structure and the depth of hardening. There had been some controversy as to the desirability of a strong or weak core, and it was noteworthy that in aeronautical and automobile engineering where lightness is an essential, strength must not be obtained by increasing weight. There is a certain amount of truth in the popular idea that "once the case is broken the core does not matter"—at all events, an alteration of the strength of the core does not affect the tensile or compressive strength, though it has been found that fracture always occurs at a point corresponding with the core's yield point. Consequently, the raising of this yield point reinforces the case and improves the quality of the whole section. Undoubtedly the impact test pointed to the need of a strong core, and was generally used for measuring toughness. In such an article as a camshaft, where the cam faces alone were hardened, and the intermediate parts unhardened, a high degree of tensile strength is desirable. In determining toughness, which the lecturer considered a very difficult property to define, "fiber" certainly plays an important part, but a fibrous core, while standing up well under a tensile test, does not necessarily resist impact when measured at right angles to the fiber, and therefore the structure should be, as far as possible, of a homogeneous nature.

Dr. Aitchison emphasized the comparative values of cooling methods, mentioning the opinion held by some metallurgists that "when once the temperature attained in refining the core has brought about the required construction, the cooling method is immaterial." From an engineering viewpoint, however, water-cooling has given strengths amounting to 6,000 to 8,000 lb. higher than those resulting from air-cooling. In earlier days, when very mild steels were employed, water-cooling had been universally employed, though steels are now of such vastly improved quality that air-cooling gives satisfactory results in the majority of cases, and is to be recommended whenever possible.

Current Events

in the Chemical and Metallurgical Industries

Dye Embargo Eliminated as Tariff Passes the House

As predicted by the Committee at the time the tariff bill was introduced, it passed the House of Representatives on July 21 by a substantial majority. In the final vote of 289 to 127, the division was almost completely along party lines. The Longworth embargo on dyes, which was the first of the five sections to receive the separate vote of the entire House, was defeated by the scant majority of 16 votes. Oil, hides, cotton and asphalt all remained on the free list of the bill in its final form. The measure now goes to the Senate when it is reported that the Finance Committee will hold extended hearings and will probably postpone final action on the bill until fall, pending consideration of tax legislation.

The chemical schedule came in for somewhat more than its share of discussion, for under the special cloture rule obtained by the Committee, three of the five sections open to amendment related to chemical products. These were dyes, petroleum and asphalt. The great preponderance of debate centered on the Committee's proposed 3-year embargo on dyes and coal-tar chemicals. After three days of heated debate, the House on July 16, voting as a committee of the whole, refused to accept any amendments to the section by a vote of 122 to 109. When the entire bill was called up before the House proper on July 21, however, Representative Frear moved that all of par. 27 which provided for the embargo control be eliminated from the chemical schedule. A number of Democrats, who had previously supported the measure, swung to the opposition and succeeded in defeating the embargo by a vote of 209 to 193. In the bill as passed by the House, coal-tar crudes remain on the free list, intermediates receive a protective duty of 30 per cent plus 7c. per lb., and dyes and finished coal-tar products are dutiable at 35 per cent plus 7c. per lb.

CHANGES IN CHEMICAL SCHEDULE

Among other last-minute changes in the bill was the increase in the duty on citrate of lime from 2½c. to 7c. per pound. Citric acid, which should logically have received a greater compensatory duty, was raised only to 12c. An important change was made in the rate on camphor which the Committee had fixed at 25 per cent ad valorem. Crude camphor remained dutiable at 1c. per lb. as in the present law while the rates on refined and synthetic were increased to 6c. per lb. The duty on ethyl alcohol was changed to 15c. per proof gallon. The quicksilver tariff was increased 500 per cent on the recommendation of the Secretary of War and a compensating increase on vermilion reds was approved.

The provision for a duty on imported petroleum oil was defeated after a sharp conflict between representatives from New England and from Oklahoma and Kansas, the centers for the independent oil producers. Following the reading of a letter from President Harding, Representative Treadway, of Massachusetts, succeeded in obtaining the passage of an amendment to return petroleum to the free list.

Asphalt was also returned to the free list after the House had rejected various proposed duties ranging from 50 cents to \$3 per ton. The committee later introduced some 200 so-called "perfecting" amendments, most of which were designed to correct spelling and other minor inconsistencies although in certain cases substantial increases in rates were included.

Following the scathing denunciation of the dye bill in his recent minority report, Congressman Frear of Wisconsin led a vigorous attack on the measure and was supported on

the floor of the House of Representatives by Burroughs of New Hampshire, Black of Texas, Fish of New York, Tague of Massachusetts and Moore of Virginia.

DYE EMBARGO DEFENDED BY LONGWORTH AND OTHERS

The bill was ably defended in speeches by Representatives Longworth, Copley and Hadley, who composed the sub-committee in charge of chemicals. Others to take up the fight in favor of special protection for the dye industry included Green of Iowa (who was largely responsible for the legal features of the measure); Treadway of Massachusetts, Graham of Illinois, Snyder and Magee of New York, and Tilson of Connecticut.

Representative Frear on a number of occasions charged that the dye industry was a half-billion dollar monopoly, represented largely by the Chemical Foundation, which was characterized as a private company that had defrauded the government of \$10,000,000 worth of patents. Frear also continued his attack on the officials of the Foundation.

In replying to Mr. Frear, Representative Longworth pointed out that only a very small proportion of the dyes produced in this country were affected by the Foundation's patents, and while offering no defense of the corporation, he explained its organization and principles. The Tariff Commission's report on dyes in 1920 which is referred to on page 166 of this issue, was quoted to show that no monopoly existed in the industry. In referring to the important relation to the National Defense, reference was made to the messages of former President Wilson, and the following letter from General Pershing was read:

GENERAL OF THE ARMIES,

Washington, July 15, 1921.

Hon. NICHOLAS LONGWORTH,

House of Representatives, Washington, D. C.

DEAR MR. LONGWORTH: With reference to the protection for the dye industry in this country, it can be stated that the coal-tar products, of which dyes are the most important at present in peace, is the base of practically all of our high explosives and most of our war gases.

Our shortage of chemical plants in general, and dye plants in particular, prior to the World War, made it difficult for us to obtain a supply of high explosives and gases until we had been in the war for several months.

From the above the importance of the chemical industry from a military standpoint will be readily seen.

Sincerely yours,

JOHN J. PERSHING.

PROTESTS AGAINST POTASH AND OTHER DUTIES

An idea of the opposition certain to meet the potash duty in the Senate may be gained from the remarks in the House—where it did not come up for a separate vote—by Representative Larsen, of Georgia. "The domestic potash industry," said Mr. Larsen, "has been in existence five years. For four years, it has enjoyed a complete monopoly and prices have been the highest in the history of the country, yet it has never produced more than twenty per cent of our normal demand. If at \$500 per ton, the industry were able to produce only 20 per cent of the normal demand, how is it going to produce potash under present conditions so it will be profitable to the industry or to the consumer?"

Among other duties to be protested are the proposed levies on vegetable oils, including olive oil. The soap manufacturers and other consumers have organized a bureau of free raw materials and have appealed to the President for more liberal tariff treatment for the materials entering into the manufacture of soap, lard and butter substitutes, paints, leather and allied materials.

Census of Dyes and Coal-Tar Chemicals for 1920

The fourth annual report on the production of dyes and other coal-tar products during 1920, which has been issued recently by the United States Tariff Commission, shows remarkable developments in these important industries. The progress made during the year is evidenced by the fact that the output of dyes increased over 40 per cent, reaching a total of 88,263,776 lb., valued at \$95,613,749. This exceeds the imports of 1914 by 92 per cent. In general the dyes used in large quantities were made in amounts sufficient to supply American needs. A number were made in considerable excess of domestic requirements and this contributed to the development of a large export trade in dyes during 1920. The American manufacturer, having met the demand for the dyes consumed in largest quantities, is now turning his attention toward the production of the many so-called "specialties," which while of secondary importance as far as quantity is concerned, are nevertheless essential to the establishment of a well-rounded and self-contained dye industry.

INTERMEDIATES AND DYES

The quantity of intermediates produced in 1920 showed an increase of 45 per cent over the output in 1919. The total production was 257,726,911 lb., valued at \$95,291,686. Of the more fundamental intermediates, aniline oil increased 61 per cent over the 1919 figure; beta-naphthol, 147 per cent; dimethylaniline, 53 per cent; gamma-acid, 170 per cent; H-acid, .35 per cent; alpha-naphthylamine, 233 per cent; paranitraniline, 63 per cent; and benzidine base, 91 per cent.

The production of anthraquinone increased from 294,260 lb., valued at \$547,787, in 1919 to 539,619 lb., valued at \$894,418. This increase is due in part to the development of synthetic anthraquinone from phthalic anhydride and benzene.

Triphenylphosphate and tricesylphosphate, used as substitutes for camphor in pyroxylin plastics, first appeared in 1920. It is doubtful whether these products can replace camphor for all purposes, but they at least offer a possible means of becoming independent of the Japanese camphor monopoly.

There were 360 or more different dyes produced by eighty-two American manufacturers in 1920. The output of these dyes, by classes according to their method of application, is shown in the accompanying diagram, which also offers a means of comparing this production with that of previous years (1917, 1918 and 1919) and with the imports for 1914 and 1920. The pre-war imports, which in many

cases have been more than doubled, are exceeded for all classes except for "vat dyes other than indigo." That real progress was made in this class, however, is evidenced by the increase from an output of 389,158 lb. in 1919 to 1,159,868 lb. in 1920. The output of indigo, 18,178,231 lb., valued at \$13,497,981, exceeds the production of 1919 by 105 per cent and is 116 per cent greater than the importations during 1914. Sulphur black, which has previously been the first color in quantity produced, ranks second in 1920 with an output of 16,305,037 lb.

PRODUCTION AND IMPORTS

A significant fact shown by the Tariff Commission's report is that of the 360 dyes produced in 1920, 108 individual colors, representing 92 per cent of the total output, were each manufactured by three or more firms. Of still greater significance is the fact that thirty-five dyes amounting to 52 per cent of the total, were each manufactured by seven or more separate firms. The dyes manufactured by only one firm numbered 200, but their output represented only 5 per cent of the total domestic production.

It is interesting to note that a consideration of the value of production, imports and exports shows that the value of the domestic output in 1920 was equal to at least 120 per cent of the domestic consumption, or exactly double the 60 per cent requirement of the tariff act of Sept. 8, 1916.

Among the other finished products derived from coal tar, there were conspicuous increases in the output of synthetic tanning materials, color lakes, perfume materials and synthetic phenolic resins. Some progress was reported in the manufacture of photographic chemicals, but there were marked decreases in the case of coal-tar medicinals and flavors.

In addition to the detailed production statistics, the report contains an analysis of dye importations, which classifies the foreign colors according to Schultz numbers and shows their manufacturers, quantities imported, invoice values and countries of origin. The results of this study had already been outlined in a preliminary statement by C. R. DeLong of the Tariff Commission's staff, which was published in *CHEM. & MET.*, vol. 24, p. 845, May 11, 1921.

Other features of the report include the studies of rates of pay to employees with and without technical training, and also the amounts spent for research by the different manufacturers. The proportion of the monthly output of the German dye plants which is reserved for the option of the Reparations Commission is shown for the last eleven months of 1920 and the first three months of 1921. The appendix of that report includes a directory of the domestic manufacturers of coal-tar products during 1920.

FIG. 1. — COMPARISON OF PRODUCTION AND IMPORTS OF DYES BY CLASSES

□ PRODUCTION 1917 TO 1920 INCLUSIVE

C. R. DELONG. 6-15-21.

Fixed Nitrogen Research Laboratory

The Department of Agriculture has authorized the following official statement in connection with the transfer of the Fixed Nitrogen Research Laboratory from the War Department to the Department of Agriculture. The statement follows in its entirety:

By an order of the President, the Fixed Nitrogen Research Laboratory in Washington, D. C., established for war purposes in 1919, has been transferred from the War Department to the Department of Agriculture. This means that the research work to discover methods of fixing nitrogen from the air and making it available for use will be continued, and the results will be available for agricultural and chemical purposes.

The War Department, in making the transfer, included a provision, which was approved by the President, that the work of the laboratories should be available for the War Department at such times as national defense should make it imperative. A personnel of 110 to 120, including 50 of the best-trained experts in the world in nitrogen fixation and the application of the product, is transferred from the War Department to the Department of Agriculture, with the assurance that this carefully selected group of workers will be kept together instead of drifting into private occupation.

Dr. R. C. Tolman, Director of Fixed Nitrogen Research, will remain in the same position. The method of control of the research work under the Department of Agriculture has not been worked out in detail. The sum of \$500,000 made available from funds in the control of the President is transferred for the maintenance of the work for the next two years.

The laboratory is located on the grounds of the American University on Massachusetts Ave., Washington, making use of buildings and equipment formerly used by the Research Division of the Chemical Warfare Service. The largest building in use is loaned by the American University.

The Fixed Nitrogen Research Laboratory was founded by an order of the Secretary of War dated March 29, 1919, and has been operated with a budget of \$300,000 a year, the funds being provided under the National Defense Act of June 3, 1916, which authorized the President of the United States to "cause to be made such investigations as in his judgment are necessary to determine the best, cheapest, and most available means for the production of nitrates and other products for munitions of war and useful in the manufacture of fertilizers and other useful products, by water power or any other power, as in his judgment is the best and cheapest to use."

WORK OF THE LABORATORY

The main work of the laboratory has been to study the fixation of nitrogen by the cyanamide, the Haber and the arc processes, and to study the methods of transforming the various forms of nitrogen-containing products so as to make them most available for military, agricultural or industrial uses.

The cyanamide process is the one designed to be used at the Muscle Shoals plant in Alabama, and the Haber process in the smaller Sheffield plant in the same state, while the arc process is regarded as one of the most important processes of nitrogen fixation from a military point of view, since it can be most rapidly installed in case of war, and since it provides nitrogen at once in the nitrate form without the necessity of any oxidation from the ammonia form. The Government owns no arc plant, and for this reason less attention has so far been given to this process than to the others.

The cyanamide process is one of the best-known and best-established methods of fixing nitrogen, and the laboratory has completed more work in connection with this process than with the other methods of nitrogen fixation. The cyanamide process is at present the only process by which nitrogen can be fixed in America in case of emergency. The work on cyanamide was originally undertaken at the specific direction of the Fixed Nitrogen Administrator, Arthur Graham Glasgow, because of the Government ownership of the great Muscle Shoals plant, which is expected to produce 220,000 tons of cyanamide per annum.

The main purpose of this work has been to study cyanamide and its various possible transformation products from the point of view of their utility in agriculture, explosives and the arts. The laboratory has already collected an enormous amount of information as to the various compounds which can be prepared from this material. A large amount of further information is now coming through in the form of additional reports, and a number of important experimental investigations are being brought to a close. Experts in the Washington laboratory believe that the cyanamide process will remain an important method of fixing nitrogen for many years to come.

The Haber process, which under certain industrial conditions can displace the cyanamide process, has never been commercially operated outside of Germany. It has very great inherent difficulties connected with handling large quantities of flammable gas at high pressure and high temperatures.

While the research laboratory was established under the War Department and with a particular view to working out explosives problems, the necessity of obtaining a nitrogen supply for agricultural purposes has been kept constantly in mind. Pot and field tests have been carried on in co-operation with the Bureau of Plant Industry of the Department of Agriculture and at the two Alabama plants, where 20 acres were given over to agricultural tests in 1920. The closest co-operation has been maintained between the two departments in this work, and Dr. R. O. E. Davis, Scientist in Charge of Soil Physical Investigations of the Bureau of Soils, has been assigned for some time to co-operate with the work at the laboratory. Samples of fertilizer material for next year's tests at the plants are now being prepared by the laboratory.

Owing to the great variability in the results obtained in field tests, the experts are very anxious to continue the work for another year. The laboratory has already collected very important information as to the behavior of about 10 nitrogen-containing substances to these field tests.

NEEDS OF NITROGEN SUPPLY

Nitrogen is one of the three great elements necessary in fertilizers for plants, the others being phosphoric acid and potash. Nitrogen forms an essential constituent of explosives, of fertilizers, of dyestuffs, and many other substances used in the arts. In time of war the necessity of importing Chilean saltpeter, with its attendant uncertainties and tie-up of carrying capacity, was very serious. In time of peace the use of nitrogen in fertilizers is limited only by the supply and, if available, larger quantities would be used for increasing the food and other crops necessary for the country's welfare. It has been estimated by a high authority that the total loss of nitrogen from the arable land under cultivation in the United States is equivalent to 15 to 20 million tons of ammonium sulphate a year, representing a material work of about \$1,000,000,000.

A peculiarity of nitrogen fixation research in contrast to many other lines of scientific investigation is the rigid secrecy maintained by each country because of the great advantage of a supply of fixed nitrogen in time of war. Thus, although Germany has carried on extensive research for years, the results have not been made available and it has been necessary for the American scientists to start from rather rudimentary beginnings and build. The laboratory and personnel are considered the best on this continent, and possibly in the world.

Slate Industry Utilizing Waste

Theories for utilizing waste at slate quarries are being put into practice quite generally, according to Dr. Oliver Bowles, of the U. S. Bureau of Mines, after a visit to a number of quarries in the East and in New England. One large quarry is at this time installing a grinding plant to produce a 200-mesh product for filler purposes. There is an increasing demand for this type of material for filler in roofing and linoleums, and in asphalt mixtures.

While the activities at slate quarries are at a low point at present, steps are being taken in preparation for an increased volume of business which it is believed is certain to come with the increase in building activities.

Secretary Hoover Comments on Ford's Muscle Shoals Offer

The Secretary of Commerce revealed on July 18 that Henry Ford is not the only private interest considering the Muscle Shoals power proposition. Secretary Hoover stated that various chemical and power companies were considering the matter and indicating an active interest in it.

The Henry Ford proposition, and this has been confirmed at the Department of Commerce, is as follows: Mr. Ford offers to lease for 100 years the Wilson dam and the nearby No. 3 dam, along with the electrical installation, when the project is completed. It is estimated that an additional \$28,000,000 must be expended for the completion of the dam. On that sum, Mr. Ford proposes to pay interest at the rate of six per cent, and to amortize not only this sum but the entire cost of both dams over a period of 100 years. In addition he offers \$5,000,000 for the outright purchase of nitrate plant No. 2, its auxiliary steam plant, the land necessary to the operation and other appurtenances. He agrees to operate the nitrate plant for the production of fertilizers and to make the necessary conversion of the plant. He agrees also to maintain the plant so that it may be converted promptly for the manufacture of explosives in case of war. The plant is to be kept up to date in both arts. He agrees also to limit the profits of the fertilizer plant to eight per cent.

Mr. Ford expects to use a part of the power not needed for the nitrate plant for some of his own manufacturing enterprises and in addition it is assumed that he will undertake to find buyers for the surplus power. The Secretary of Commerce authorized the following statement in regard to Mr. Ford's proposal:

"The acceptance of the offer is matter for decision by Congress and that body will no doubt be greatly guided by Secretary Weeks' views in the matter. Mr. Ford has made a genuine proposal. It shows courage to agree to pay out \$5,000,000; to spend further sums upon large works and besides to take an annual obligation for about \$1,500,000 for 100 years and to agree to maintain a nitrate plant in reserve for the government for that period. Whatever may be the result, Mr. Ford's offer does prove what the public associations have contended—that the completion of this project has a commercial value."

Minerals Separation North American Corporation a Party to Miami Suit

On July 15, 1921, Judge Morris, in the U. S. District Court, Wilmington, Del., granted the petition of Minerals Separation, Ltd., and Minerals Separation North American Corporation that the latter company be made party in the suit in Minerals Separation, Ltd., vs. Miami Copper Company.

The granting of such a petition is of very little general interest since it matters not just which of the various corporate organizations of Minerals Separation, Ltd., are or are not parties in this suit.

But had Judge Morris, upon the other hand, found, as was claimed by the Miami Copper Company, that Minerals Separation had upon July 8, 1913, actually transferred its legal interest in its patents to the American corporation some very interesting and possibly far-reaching questions would have arisen as to the status of the suit now being prosecuted and also as to the disclaimer made by Minerals Separation, Ltd., as to certain claims of patent 835,120.

Stanley Patent Bill Again Delayed

The Stanley patent bill, requiring foreigners who take out American patents to undertake manufacture within the United States, was reached on the Senate calendar July 18, but was not considered, due to objection on the part of Senator Smoot, of Utah. Senator Smoot said that he had taken up some phases of this legislation with the Commissioner of Patents and is awaiting a reply. Pending receipt of that reply, he asked that the legislative consideration of the bill be postponed.

Another Moses Amendment

In explaining an amendment, which he has offered to the section of the Fordney tariff bill relating to dyes and coal-tar products, Senator Moses said:

"I propose to eliminate the embargo feature which the monopolistic dyestuff makers of America insist upon having in violation of the promises repeatedly made to committees of Congress in both Houses, and to give them instead a straight tariff protection in an amount wholly sufficient to cover the adverse labor costs obtaining in European countries, and adding a sufficient protection to give American dyestuff makers a consistent advantage in those markets. I intend to amplify this amendment in the course of the debate in the Senate when the tariff bill comes to us; and my only comment is that any manufacturer desiring a larger measure of protection than my amendment provides for him is a consummate hog."

The tariff protection provided in Senator Moses' amendment is accomplished by substituting for the ad valorem rates on dyes and intermediates, a special duty equal to the amount by which the American selling price plus 20 per cent of such price shall exceed the foreign market value to which has been added the specific duty of 7 cents per pound and certain non-dutiable charges for shipping and packing. In other words, the duty provides for the spread between the foreign and domestic prices and then adds an additional 20 per cent of the latter price. A foreign dye, under such an arrangement, will cost at least 20 per cent more than the identical American product. In case there is no comparable American dye or the foreign market value can not be determined, the amendment proposes alternative procedures based on costs of production.

The United States Tariff Commission is to supply the Secretary of the Treasury with the information required by the collectors of customs for the administration of the suggested measure.

Fall Meeting, American Electrochemical Society

In accordance with its policy of planning technical sessions well in advance so that members having research under way or papers in prospect will have an opportunity to complete them, the American Electrochemical Society has decided to hold a symposium on gases of the electrochemical industries at its spring meeting in 1922. The subject will include gases produced directly by electrolysis, their properties and uses; byproduct gases, their properties and uses; gas produced from electrochemical and electrothermal products, their generation, properties and uses. W. S. Landis, 511 Fifth Ave., New York City, is in charge of the symposium. Particular attention should be paid to new processes of generation, new uses and particularly to a compilation of newly discovered properties or of revised constants of the various gases in question.

It is announced that plans for the Lake Placid meeting, September 29, 30 and October 1, are proceeding satisfactorily. Lake Placid is recognized as a delightful mountain resort, and members of the society will find this meeting highly enjoyable. Plans are under way for outdoor sports in addition to the technical sessions. The latter will include symposia on non-ferrous electrometallurgy and electrodeposition.

Plans for Fall Meeting, Dye Division, A.C.S.

On Wednesday and Thursday, September 7 and 8, the Dye Division of the American Chemical Society will hold its fall meeting in New York City. This and other divisional meetings will be held in the buildings of Columbia University.

In addition to the usual scientific program, there will be an election of officers, and also discussion relating to matters of interest to the Dye Division.

An unusual effort will be made this fall to have the scientific papers read before the division of considerable interest. The secretary, R. Norris Shreve, 43 Fifth Ave., New York City, asks members to let him know at once about any papers which they can present, pertaining to the chemistry of the manufacture, use or application of dyes and intermediates.

Fermogas Promoter Sent to Prison

Stanislaus C. Papp, 41 years old, a chemist, who in May, 1920, caused a stir when he announced he had discovered that the juice of corn stalks, plus a little sugar, could be made into a substitute for gasoline in the operation of automobiles, was sentenced to from two and a half to five years in Sing Sing when arraigned before Judge McIntyre on July 19.

He had pleaded guilty to six indictments charging him with posing as "Professor F. John Chassler" when he induced many poor Hungarians and others to purchase stock in the Fermogas Company, a \$1,000,000 corporation, which he organized after he had given several fraudulent demonstrations of his "discovery" to army officers, bankers and capitalists in Ramsey, N. J.

Assistant District Attorney Lazarus told Judge McIntyre that the "professor" opened an office at 10 East Thirty-ninth Street for the disposal of stock in his "fermogas" company to victims, and that he maintained a "laboratory" at his home at 5,614 Second Avenue, Brooklyn. He gave a demonstration of his "product," Mr. Lazarus said; but it was found later that the "professor" had an old pipe running to the vat containing the ingredients for the gasoline substitute which pumped perfectly good gasoline into the automobile in which he gave his demonstration.

New York Meeting, American Chemical Society

The fall meeting of the American Chemical Society will be held with the New York Section, Tuesday September 6 to Saturday, September 10. This will probably be the largest meeting of the American Chemical Society that has ever been held. Aside from the 2,500 members of the New York Section itself, many thousands are within a four or five hours' ride of New York. In addition to the usual features the society will have as guests at this time a considerable number of British and Canadian members of the Society of Chemical Industry who will have held their annual meeting in Canada, will be greeted at the border by the Governor of the State, and will arrive in New York on Wednesday morning, September 7. After being the guests of the American Section of the Society of Chemical Industry at a Luncheon September 7, they then become the guests of the American Chemical Society for the remainder of the week. At least three or four hundred of these British and Canadian friends are expected, besides three or four thousand from the American Chemical Society. All members of the American Chemical Society are invited to the meeting in Montreal, beginning August 29th.

A further reason for this being a large and successful meeting is the opening of the National Exposition of Chemical Industries on September 12, immediately after the close of the meeting. A great many guests from all over the United States who visit this Exposition each year, will come a few days earlier to attend the meeting of the American Chemical Society.

DIVISIONAL PROGRAMS

All Divisions will meet. Meetings are also announced of Sections of Sugar Chemistry, Cellulose Chemistry, Leather Chemistry, Petroleum Chemistry, and Chemical Education. All Divisions and Sections will have two full days at their disposal.

The Division of Industrial and Engineering Chemistry calls especial attention to two items on its program: First, a symposium on filtration, being organized by D. R. Sperry of Batavia, Ill.; and second, a symposium on gas chemistry being organized by a committee of which R. S. McBride, Colorado Building, Washington, D. C., is secretary.

Notice of the Dye Division's plans will be found elsewhere in this issue.

The Division of Chemistry of Medicinal Products will devote the largest portion of their time to a discussion of the "newer synthetics as used in medicine."

The Division of Biological Chemistry will hold an all-day symposium on vitamins with Prof. H. C. Sherman as chairman. Tentative plans include discussion of fat-soluble A, water-soluble E, antineuritic vitamin, antiscorbutic vita-

mine, stable forms of vitamin, the physical chemistry of vitamins, and vitamins from the standpoint of structural chemistry. Among the speakers will be such authorities as Mendel, Osborne, Hess, McCollum, Emmett, Seidell, Steenbock, Funk, Dutcher, Williams, La Mer, and Blunt. The great interest in the vitamin papers presented at Rochester has led the officers of the division to anticipate an unusually interesting symposium and valuable discussions.

The Cellulose Section will hold a symposium on cellulose esters. Reports by the committee on viscosity standards and by the committee on the preparation of a standard cellulose will be received.

The Leather Section already has some twenty-five papers in hand for the meeting of that section.

The meeting of a Section on Chemical Education with Edgar F. Smith as chairman and Neil E. Gordon as secretary has been authorized for the New York meeting.

The Petroleum Section will hold a symposium on emulsification problems in the petroleum industry.

Bureau of Chemistry Directorship Unattractive to Many

In feeling out a considerable number of men prominent in the field of agricultural and food chemistry and in organic research, officials of the Department of Agriculture are finding that few of these chemists are in a position to accept appointment as Chief of the Bureau of Chemistry at \$5,000 a year. In private industry a chemist capable of directing the work of 300 technical men and 400 other assistants receives a salary of several times \$5,000. Many chemists of this type would be glad to do public service if they could afford it, but it is apparent from the investigation which the department has made that not many men are in a position to make this sacrifice.

The resignation of Dr. C. L. Alsberg became effective July 15. At the request of the Secretary of Agriculture he remained in Washington for a number of days after that date but the fact that his new duties at Leland Stanford require his early presence in California precludes his devoting more time to the bureau. This is expected to hasten the matter of selecting the new chief. The problem admittedly is simply one of persuading some properly qualified chemist to work for \$5,000 a year.

Chemical Exposition Notes

FILTERS

In the approved methods of today efficiency in every branch of factory or plant is demanded. In filters, the advantages looked for are labor saving, saving of filter cloths, perfect filtration, low cost of maintenance, perfectly clear filtrate, clean installation, high capacities, low moisture content.

All of these requirements have been met by exhibitors of filters at the Seventh National Exposition of Chemical Industries, Eighth Coast Artillery Armory, New York, Sept. 12 to 17. An open tank filter which requires only one man to operate hundreds of square feet of filter area will be one of the exhibits.

A rotary continuous suction filter, superior for handling mud from hot, caustic solutions from continuous causticizing and lime recovery is a typical American product.

Large sums are spent annually by manufacturers experimenting with the clarity and keeping quality of their products. The opportunities for research and investigation at the exposition will be invaluable in obtaining filtering efficiency.

Platinum Theft at Sierra Magnesite Co.

The Sierra Magnesite Co., Porterville, Cal., reports the theft of platinum from its laboratories some time during the night of June 14, comprising three platinum crucibles weighing, respectively, 12.1 g., 12.328 g., 14.307 g. In addition to these there was taken one palau crucible weighing 14.491 g.

Personal

DR. HARDEE CHAMBLISS has been placed in charge of the Department of Chemistry of the Catholic University, Washington, D. C. He will be in immediate charge of the Martin-Maloney laboratory. Dr. Chambliss was graduated from Johns Hopkins University in 1900. He has devoted practically his entire time since in chemical research and instruction. During the war he was in charge of the Government's nitrate plant No. 1 at Sheffield, Alabama. Dr. Chambliss succeeds Rev. John J. Griffin, who has been in charge of the University's Department of Chemistry since 1895. Dr. Griffin was compelled to abandon the work on account of ill health.

W. J. CROOK, formerly chief metallurgist of the Pacific Coast Steel Co., has been appointed associate professor of metallurgy at Stanford University. Mr. Crook is retained by the steel company in a consulting capacity.

DR. GRAHAM EDGAR of the University of Virginia is associated with the research work of the Fixed Nitrogen Research Laboratories, American University, Washington, for the summer. Dr. Edgar previously was connected with this organization and has returned to the work to round out some of the investigations in which he has been engaged previously.

O. B. HOFSTRAND, metallurgical engineer, of Salt Lake City, Utah, has recently returned after having completed an extensive investigation of the Tintic Milling Company's plant and process at Silver City, Utah.

DR. R. B. MOORE, chief chemist of the U. S. Bureau of Mines, will leave Washington August 2nd for a month's trip during which he will look over the chemical phases of the work being done at Bureau of Mines experiment stations at Pittsburgh, Columbus, St. Louis, Denver, Salt Lake City, Reno, and San Francisco.

DR. WALTER F. RITTMAN is to assume duty as head of the Department of Commercial Engineering, Carnegie Institute of Technology, Pittsburgh, Pa., next fall.

WELD, LIDDELL & LAZENBY have dissolved the partnership. Messrs C. Minot Weld and Donald M. Liddell will continue to practice as consulting engineers and economists under the name of Weld and Liddell, at 2 Rector Street, New York. Paul H. Lazenby will continue his practice independently in transportation business, public utilities and economics, with offices at 2 Rector Street, New York.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, July 22, 1921.

Chemicals are finding a quiet outlet in most instances and price changes have been confined to comparatively few items. Second hands have been kept moderately active, but they are not getting any real assistance from consumers who prefer to operate only for necessary requirements. Prices advanced slightly at intervals then declined to where they were previously. The movement depended chiefly on whether the principal wanted to buy or sell. Looking at the big basic chemicals, we find a slight shading of prices for resale *caustic soda* at the works. This is not due entirely to speculative short selling, as some of the more prominent dealers have sold down to 3½c. per lb. against a 4c. price at the close of the previous week. The market has been well restricted on resale stock to the range of 3½@4c. per lb. Offerings of large tonnages of German *caustic soda* at \$3.35 per hundred lbs. attracted considerable attention and found ready buyers. *Soda ash* has not been altered to any noticeable extent on spot. Prices

ranged from \$2.05@\$2.10 per 100 lb. and closed at the inside figure in single bags in most resale quarters. *Bleaching powder* was handled to some extent for paper mills at \$2@\$2.10 per lb. f.o.b. works and closed rather firm at these prices which were named by large dealers. *Bichromate of soda* showed a slight decrease at the close of the week. *Oxalic acid* remained fairly steady and appeared to be somewhat under control. Aside from tartaric acid, the smaller items were quite steady with camphor, quinine and menthol showing a disposition to strengthen. *Prussiate of soda* slumped about ½c. per lb. under keener competition. *Caustic potash* was easy while imported *chlorate of potash* seemed a bit steadier. *Copper sulphate* was in moderate request remained steady. Second hands are quoting producers' prices on standard quality and it looks as though resale supplies of this chemical have been well liquidated.

Textile mills are buying some material and a better feeling has developed in the tanning industry. The usual depression in business has been reported from the glass plants where summer slackness has been in order. Paper mills seem to be buying more freely and quite a few inquiries have resulted in the placing of some large orders. There are distinct indications of a moderate increase in the volume of the general merchandise business. The building trade has taken a decidedly better turn and this condition has developed an increased demand for building materials. There has been some noteworthy improvement in the credit situation. All danger of a credit strain has definitely passed. The general condition of business in this country is greatly disjointed, but there is no serious alarm for a general depression. Although the copper mines are closed down and the steel industry is operating at 25 per cent capacity, these industries as well as others cannot through any possibility remain permanently stagnant.

CHEMICALS

Producers of *acetate of soda* report sales on the basis of 4c. per lb. and quote the market 4@4½c. depending on quantity. This is the lowest price quoted in the open market so far this year and compares with a high price of 12½c. established in May, 1920, and a high price of 6½c. recorded in January and February, 1921. First hand sales of *bicarbonate of soda* are going through on the basis of 2½c. per lb. f.o.b. works in barrels and 2½c. per lb. in kegs. Dealers are offering prime material at \$2.35 per 100 lb. in bbls. ex-store and report a rather calm market. Spot *bichromate of soda* appeared somewhat steadier at the close and 8c. per lb. was the minimum for standard material. Sellers reported quiet trading at 8@8½c. per lb. Most dealers of *caustic soda* quoted the market for standard brands at \$4@\$4.15 per 100 lb. ex-store N. Y. At the works dealers quoted 3½@4c. per lb. depending upon the quantity. Contracts are quoted by producers at 3½c. per lb., basis 60 per cent, f.o.b. works. Moderate trading has featured the market and transactions have been along conservative line in most instances. Some German *caustic soda* was offered at \$3.65 per 100 lb. ex dock N. Y. Manufacturers report sales of *hyposulphite of soda* at 3½c. per lb. in bbls. for carload lots. Smaller quantities are moving at prices ranging up to \$3.85 per 100 lb. A fair inquiry has reached the market during the past week. Spot *nitrate of soda* was offered at 7@7½c. per lb., while some sellers are asking above this figure. Light trading is about the best that can be said of the market at present and the desire to secure new business has prompted slight price shading in some directions. Lower prices are reported for *prussiate of soda* on spot. Sales have been rumored down to 11½c. per lb., but the general quotation was 11½@12c. per lb. according to quantity. This is another chemical that has felt the depressing influence of selling competition. Buyers are chiefly interested in small lots. Dealers' prices on resale light *soda ash* in single bags range from \$2.05@\$2.10 per 100 lb. Barrels were offered at \$2.40@\$2.50 according to seller and quantity. Resale offerings at the works were quoted at \$1.85@\$1.95 per 100 lb. First hand prices at the works were heard at \$1.60 per 100 lb. for single bags, basic 48 per cent. Imported ash was obtainable in limited quantities at \$1.55 per 100 lb. ex-dock N. Y. Prime domestic *sulphide of soda*, fused, is quoted by producers at 6½c. per

lb. which resale material has been offered at prices ranging from 5@5½c. per lb. The broken variety is quoted at 5½@6½c. per lb.

Business in *barium chloride* has shown a little more activity of late with dealers holding spot material at \$59@ \$60 per ton. Sales for immediate shipment from abroad were reported at \$55@\$57 per ton. Producers of *bleaching powder* continue to ask 2¼c. per lb. for large drums at the works regardless of rumors to the effect that lower prices have been named. Prominent dealers quote the market at \$2@\$2.10 per 100 lb. f.o.b. works and 2¼@2½c. per lb. for small drums. Miscellaneous inquiries have resulted in some additional business being placed, but buyers seem to be far enough under sellers' ideas to prevent extensive business. Producers report sales of *glaubers salt* in bags at 1½c. per lb. in carload lots. These interests are asking 1¾c. per lb. for smaller quantities. Spot oxalic acid is quoted from 18@19c. per lb. according to seller and quantity. It is somewhat possible to purchase a few odd lots at 17¾c. per lb. Producers quote the market at 17¾c. per lb. and upward f.o.b. works. The tone of the general market is steady with a fair number of inquiries reported in several quarters.

COAL-TAR PRODUCTS

There is a growing disposition among the larger producers to maintain prices more firmly, not so much with the idea of holding the market at present prices, as to stabilize conditions and drive out all superfluous resale stock which threatened for a time to cause a serious depression in present prevailing prices. *Benzene* and *toluene* are firm, with an actual scarcity of benzene. England has been a consistent bidder for benzene for the past few months, but the fact that the facilities for loading tank steamers are controlled by the big oil firms together with curtailment of production due to the closing of many coke-ovens prevent shipments of material. One large factor reports that an average of several orders a week are being turned down due to the above causes. Prices on benzene are firm at 27@33c. per gal., with very small supplies available. Inquiries are numerous, but sales are necessarily restricted. Imports of *cresylic acid* have been more sufficient to meet requirement and surplus stocks are available, but sellers are firm in their views of 68@75c. per gal. for the 97-99 per cent and 65@70c. on the 95 per cent. The English market is steady and present replacement costs allow little room for further price concessions. The demand for *cresol* is light and the market is barely firm at 16@18c. per lb. for the U. S. P. grade. The demand for *naphthalene* from the drug field has slackened and a consequent easing of the market is noted. Flakes are offered at 7c. per lb., balls at 8@10c. Most business is in resale goods. Producers of *toluene* quote 28@32c. per gal. Although the demand for this product has been quite strong recently, supplies remain limited.

The general inside quotation on *aniline oil* is 18c. per lb. with prices ranging up to 21c. on small lots. Sales of moderate quantities at the lower price is reported. Sellers of *benzaldehyde* show considerable variance in their price views with technical at 45c. per lb., U. S. P. material at \$1.00@\$1.25 per lb. and F. F. C. at \$1.85 per lb. The demand remained dull. Producers of *benzyl chloride* report the market more active at lower prices, with the 95-97 per cent firm at 25@27c. per lb. and the technical at 20@23c. Small lot selling of *dimethylaniline* was done at 40c. per lb. and in some cases at 39c. The demand is light. Reduction on the base variety of *para-amidophenol* to \$1.40 per lb. was made. The HCl was steady at \$1.60@\$1.75 per lb. Supplies are abundant and prices show the effect of surplus stocks. A decline to \$1.60 per lb. was noted for *resorcinol* under keener competition. The demand is steady. Strong selling pressure in *beta-naphthol* is reducing prices. Supplies are more than sufficient to meet the current light demand. Prices range from 33@38c. per lb., with prospects of shading on actual business. In spite of foreign inquiries, the market on *para-nitroaniline* is easier and 75c. per lb. has been done on passing business. Current quotations range to 80c. per lb., but the lower figure is attracting all the business.

The St. Louis Market

ST. LOUIS, Mo., July 21, 1921.

The drug and fine chemical market during the past two weeks has been rather quiet and featureless, nothing of importance having transpired recently. Inquiries are still numerous but not of large volume, and the consuming trade for the present moment are not disposed to take on more than for their immediate requirements. While the movement of heavy chemicals has also been slow the past two weeks, a number of inquiries on quite a few of the items gave the market a more optimistic tone, and it is to be hoped these inquiries are but the forerunner of a general activity on all heavy chemicals. Heavy importations of foreign chemicals continue to be noted and apparently importers are endeavoring to bring in as much of the foreign material as is possible before the new tariff becomes effective. The proposed tariff has not stimulated business to any noticeable extent.

Caustic soda remains quiet with a strict adherence to the manufacturer's schedule. The inquiry on *soda ash* has been very fair and while round lots are still quoted at \$2.95 per 100 lb., sales have been reported at \$2.60 per 100 lb. *Sal soda* and *sodium bicarbonate* remain inactive.

Carbon bisulphide continues to be one of the active items with a constant flow of inquiries resulting in quite a little business. *Hypo* continues to enjoy a routine demand. *Sulphur* holds its routine demand with price remaining at \$2 per 100 lb., and less shading being reported.

DRUGS AND PHARMACEUTICALS

No change has occurred in the position of *ammonia water* 26 deg. and it continues to maintain its present schedule. Heavy importations of *bromides* are still being noted which have a very ill bearing on the domestic product and the situation at the present moment is not very promising. *Cream of tartar* is still in limited demand. *Epsom salts* is being quoted in carlots at \$2.35@\$2.50 per 100 lb., delivered, and less than carlots at \$2.60@\$2.75 per 100 lb., delivered. Factors have reduced their price on *ether* and a fair volume of business is being transacted. *Glycerine* is quoted at 14¾c. per lb., with a routine demand. The keen competition of secondhands on *iodides* seems to be gradually disappearing and giving ease to the situation. Manufacturers are hopeful that this commodity will again become firmer and on sounder basis. The *salicylates* are a seasonable article and a good volume of business is being enjoyed. A sudden and brisk demand has been experienced lately for *silver nitrate* and manufacturers are in position to meet this unexpected movement. At present *sodium benzoate* is moving slowly. However, it is anticipated that this condition should improve very shortly, in view of the approaching preserving and canning season. Quite a few inquiries for large quantities of *sulpho-carboates* have been received the past week indicating that consumers' stocks are exhausted. A steady demand for *zinc stearate* still prevails. *Zinc oxides* remain firm since their last decline. The lead-free continues in fair demand by the rubber industry while the leaded zinc oxides remain in poor demand on account of the unusually dull period the paint trade is experiencing.

ACIDS

Heavy acids are more active than in the past with a fair increase in business. *Carbolic acid* remains at its present schedule with a fair demand. Although extremely warm weather has prevailed during the past few weeks over the entire country and no doubt considerable quantities of soft drinks have been consumed, there has been no indication of an increase for the demand of *citric acid* and the situation today does not give any better appearance than some few weeks past. There has been no improvement in the call for *tartaric acid* since the last reduction.

VEGETABLE OILS AND PAINT MATERIALS

Linseed oil, after falling off a few cents, has risen sharply and holds firm at 81c. basis raw, in cooperage, ex warehouse. *Castor oil* still holds at 10½c. per lb. in drums with routine demand.

Lithopone continues to be the only pigment with a sustained demand. The price remains at 7¼c. per lb., in carlots with a 25c. per 100 lb. freight allowance.

The Iron and Steel Market

PITTSBURGH, July 22, 1921.

The Steel market has undergone a sweeping change in character. The change has occurred quietly and realization that the market is on quite a new basis may not be universal. There is a slight increase in the total volume of demand upon the mills, and prices in general average a shade lower than a week ago.

The great change is that no mill now has a fixed price. There have been times when all mills had the same price, and other times when some mills had a certain price and other mills were cutting that price by an amount which each mill determined for itself. Now there is little difference between mills but much difference between quotations on different classes of orders. A mill may quote a certain price on a carload, then quote a materially lower price on 500 tons, and then quote the first price on a carload lot again. The desirability of the order is what counts. Mills are not counting upon profits, but are weighing the loss if an order is taken against the loss if the order is not taken. The cost of production including overhead exceeds any price now obtainable, but if a mill is entirely idle there is also a loss.

Another important change in the market is that "Pittsburgh plus" or the system of basing delivered prices all over the country on a basic price at Pittsburgh, rail freight from Pittsburgh to point of delivery being added, has disappeared in several commodities that are produced in large tonnages in different districts are likely to develop a separate market price for each district.

Market prices are therefore not clear cut, since different prices are obtainable on different sizes and degrees of attractiveness of orders. Quite an ordinary order could be placed at 1.90c. for plates, shapes or bars, while a larger order would probably draw the greatest concession in plates and the least in bars.

DEMAND INCREASED

The turn has been rounded in the matter of demand upon the mills, although it requires close scrutiny to discern the change. The long decrease is interrupted and it requires no enthusiastic temperament to predict that the lowest point in demand is entirely passed, since that lowest point represented a demand less than 20 per cent of the productive capacity.

A study of the bookings, in the form of new orders and of specifications against contracts shows that the demand is widespread as to classes of buyers and also geographically, also that the bulk of the demand is in small orders, with specifications decidedly mixed in character. There is evidently represented some further progress in the liquidation of stocks of steel in the hands of jobbers and manufacturing consumers and of stocks of finished wares in the hands of manufacturing consumers. There is no improvement in railroad buying and there is evidence that the general industrial activity of the country has increased. In other words, demand upon the mills for steel was below a natural relation to the general business activity of the country, and has now begun to trend towards the natural relation, which eventually may represent something like a 40 per cent operation of the steel industry. Operations since July 1 have hardly averaged 20 per cent.

CELERITY IN SHIPMENT A DECIDING FACTOR

Prices are not a vital factor in the steel business now being placed, celerity of shipment being the important matter. The buying is hand to mouth in character and the buyer wishes to realize on the material purchased within the smallest number of days possible after he has committed himself with the mill to take the material.

Pig iron continues to recede slowly, bessemer being quotable at \$20.50, valley, basic at \$19, valley and foundry at \$19.50, valley, representing declines in the week of \$1 in foundry and 50c. in bessemer and basic. Freight to Pittsburgh is \$1.96, but some nearby furnaces would probably name lower prices delivered than the valley market plus the freight.

Sodium nitrate..... 100 lb.	2 50 -	2 60 -
Sodium nitrite..... lb.	.07 - .071	.071 - .08
Sodium peroxide, powdered..... lb.	.25 - .26	.27 - .30
Sodium phosphate, dibasic..... lb.	.041 - .041	.05 - .051
Sodium potassium tartrate (Rochelle salts) lb.		.26 - .27
Sodium prussiate, yellow..... lb.	.111 - .12	.121 - .121
Sodium silicate, solution (40 deg.)..... 100 lb.	1.00 - 1 15	1 25 - 1 40
Sodium silicate, solution (60 deg.)..... lb.	.021 - .03	.031 - .031
Sodium sulphate, crystals (Glauber's salt) 100 lbs.	1 50 - 1 75	2 00 - 2 25
Sodium sulphide, fused, 60-62 per cent (conc.) lb.	.05 - .051	.051 - .061
Sodium sulphite, crystals..... lb.	.031 - .04	.041 - .041
Strontium nitrate, powdered..... lb.	.15 - .151	.16 - .17
Sulphur chloride, red..... lb.	.07 - .071	.071 - .08
Sulphur, crude..... ton	20 00 - 22 00	
Sulphur dioxide, liquid, cylinders extra..... lb.	.08 - .081	.09 - .10
Sulphur (sublimed), flour..... 100 lb.		2 25 - 3 10
Sulphur, roll (brimstone)..... 100 lb.		2 00 - 2 75
Tin bichloride, 50 per cent..... lb.	.18 - .19	
Tin oxide..... lb.		.40 - .42
Zinc carbonate, precipitate..... lb.	.151 - .16	.161 - .17
Zinc chloride, gran..... lb.	.11 - .111	.111 - .12
Zinc cyanide..... lb.	.45 - .49	.50 - .60
Zinc dust..... lb.	.111 - .111	.111 - .121
Zinc oxide, XX..... lb.	.071 - .071	.08 - .09
Zinc sulphate..... 100 lb.	3 00 - 3 25	3 30 - 3 50

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude..... lb.	\$1 10 - \$1 15
Alpha-naphthol, refined..... lb.	1 25 - 1 30
Alpha-naphthylamine..... lb.	.35 - .40
Aniline oil, drums extra..... lb.	.18 - .21
Aniline salts..... lb.	.25 - .28
Anthracene, 80% in drums (100 lb.)..... lb.	.75 - 1 00
Benzaldehyde U.S.P..... lb.	1 00 - 1 25
Benzidine, base..... lb.	.85 - 1 00
Benzidine sulphate..... lb.	.75 - .85
Benzoic acid, U.S.P..... lb.	.60 - .65
Benzoate of soda, U.S.P..... lb.	.55 - .60
Benzene, pure, water-white, in drums (100 gal.)..... gal.	.27 - .32
Benzene, 90%, in drums (100 gal.)..... gal.	.25 - .28
Benzyl chloride, 95-97%, refined..... lb.	.25 - .27
Benzyl chloride, tech..... lb.	.20 - .23
Beta-naphthol benzoate..... lb.	3 50 - 4 00
Beta-naphthol, sublimed..... lb.	.70 - .75
Beta-naphthol, tech..... lb.	.33 - .38
Beta-naphthylamine, sublimed..... lb.	1 75 - 1 80
Cresol, U. S. P., in drums (100 lb.)..... lb.	.16 - .18
Ortho-cresol, in drums (100 lb.)..... lb.	.25 - .27
Cresylic acid, 97-99%, straw color, in drums..... gal.	.68 - .75
Cresylic acid, 95-97%, dark, in drums..... gal.	.65 - .70
Cresylic acid, 50%, first quality, drums..... gal.	.45 - .50
Dichlorobenzene..... lb.	.06 - .09
Diethylaniline..... lb.	1 20 - 1 25
Dimethylaniline..... lb.	.38 - .48
Dinitrobenzene..... lb.	.26 - .28
Dinitrochlorobenzene..... lb.	.20 - .30
Dinitronaphthalene..... lb.	.30 - .40
Dinitrophenol..... lb.	.35 - .40
Dinitrotoluene..... lb.	.27 - .30
Dip oil, 25%, car lots, in drums..... gal.	.40 - .45
Diphenylamine..... lb.	.60 - .65
H-acid..... lb.	1 15 - 1 25
Meta-phenylenediamine..... lb.	1 15 - 1 20
Monochlorobenzene..... lb.	.12 - .14
Monoethylaniline..... lb.	1 75 - 1 85
Naphthalene crushed, in bbls..... lb.	.07 - .081
Naphthalene, flake..... lb.	.081 - .091
Naphthalene, balls..... lb.	.70 - .75
Naphthionic acid, crude..... lb.	.12 - .15
Nitrobenzene..... lb.	.30 - .35
Nitro-naphthalene..... lb.	.16 - .18
Nitro-toluene..... lb.	3 10 - 3 20
Ortho-amidophenol..... lb.	.15 - .20
Ortho-dichlor-benzene..... lb.	.80 - .85
Ortho-nitro-phenol..... lb.	.15 - .20
Ortho-nitro-toluene..... lb.	.20 - .25
Ortho-toluidine..... lb.	1 40 - 1 45
Para-amidophenol, base..... lb.	1 60 - 1 75
Para-amidophenol, HCl..... lb.	

Para-dichlorobenzene..... lb.	15 - 20
Paranitroaniline..... lb.	.75 - .80
Para-nitrotoluene..... lb.	.45 - .95
Para-phenylenediamine..... lb.	1 75 - 2 40
Para-toluidine..... lb.	1 25 - 1 40
Phthalic anhydride..... lb.	.50 - .60
Phenol, U. S. P., drums..... lb.	.091 - .11
Pyridine..... gal.	2 00 - 3 50
Resorcinol, technical..... lb.	1 60 - 1 65
Resorcinol, pure..... lb.	2 25 - 2 30
Salicylic acid, tech., in bbls..... lb.	.19 - .22
Salicylic acid, U. S. P..... lb.	.20 - .25
Salol..... lb.	.80 - .85
Solvent naphtha, water-white, in drums, 100 gal..... gal.	.25 - .28
Solvent naphtha, crude, heavy, in drums, 100 gal..... gal.	.14 - .16
Sulphanilic acid, crude..... lb.	.30 - .35
Tolidine..... lb.	1 25 - 1 35
Toluidine, mixed..... lb.	.40 - .45
Toluene, in tank cars..... gal.	.25 - .28
Toluene, in drums..... gal.	.28 - .31
Xyldines, drums, 100 gal..... lb.	.40 - .45
Xylene, pure, in drums..... gal.	.40 - .45
Xylene, pure, in tank cars..... gal.	.45 - .45
Xylene, commercial, in drums, 100 gal..... gal.	.33 - .35
Xylene, commercial, in tank cars..... gal.	.30 - .35

Waxes

Prices based on original packages in large quantities

Beeswax, refined, dark..... lb.	\$0 24 - \$0 25
Beeswax, refined, light..... lb.	.27 - .28
Beeswax, white pure..... lb.	.40 - .45
Carnauba, 1-lb..... lb.	.58 - .60
Carnauba, No. 2, North Country..... lb.	.25 - .26
Carnauba, No. 3, North Country..... lb.	.131 - .14
Japan..... lb.	.16 - .161
Montan, crude..... lb.	.061 - .061
Paraffine waxes, crude match wax (white) 105-110 m.p..... lb.	.03 - .031
Paraffine waxes, crude, scale 124-126 m.p..... lb.	.021 - .021
Paraffine waxes, refined, 118-120 m.p..... lb.	.03 - .031
Paraffine waxes, refined, 125 m.p..... lb.	.031 - .031
Paraffine waxes, refined, 128-130 m.p..... lb.	.04 - .041
Paraffine waxes, refined, 133-135 m.p..... lb.	.041 - .05
Paraffine waxes, refined, 135-137 m.p..... lb.	.051 - .06
Stearic acid, single pressed..... lb.	.09 - .09
Stearic acid, double pressed..... lb.	.091 - .091
Stearic acid, triple pressed..... lb.	.10 - .101

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on earload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl..... 280 lb.	\$5 10 -
Rosin E-I..... 280 lb.	5 20 - 5 45
Rosin K-N..... 280 lb.	5 70 - 6 75
Rosin W. G.-W. W..... 280 lb.	7 35 -
Wood rosin, bbl..... 280 lb.	6 25 -
Spirits of turpentine..... gal.	.59 -
Wood turpentine steam dist..... gal.	.57 -
Wood turpentine, dest. dist..... gal.	.55 -
Pine tar pitch, bbl..... 200 lb.	
Tar, kiln burned, bbl. (500 lb.)..... bbl.	
Retort tar, bbl..... 500 lb.	
Rosin oil, first run..... gal.	.35 -
Rosin oil, second run..... gal.	.37 -
Rosin oil, third run..... gal.	.41 -
Pine oil, steam dist., sp.gr. 0.930-0.940..... gal.	\$1 80 -
Pine oil, pure, dest. dist..... gal.	1 50 -
Pine tar oil, ref., sp.gr. 1.025-1.035..... gal.	.46 -
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla..... gal.	.35 -
Pine tar oil, double ref., sp.gr. 0.965-0.990..... gal.	.75 -
Pine tar, ref., thin, sp.gr. 1.080-1.060..... gal.	.35 -
Turpentine, crude, sp. gr. 0.900-0.970..... gal.	1 20 -
Hardwood oil, f.o.b. Mich., sp.gr. 0.960-0.990..... gal.	.35 -
Pinewood creosote, ref..... gal.	.52 -

Solvents

73-76 deg., steel bbls. (85 lb.)..... gal.	\$0 41 -
70-72 deg., steel bbls. (85 lb.)..... gal.	.39 -
68-70 deg., steel bbls. (85 lb.)..... gal.	.38 -
V. M. and I' naphtha, steel bbls. (85 lb.)..... gal.	.30 -

Crude Rubber

Para-Upriver fine..... lb.	\$0 16 - .17
Upriver coarse..... lb.	.09 - .091
Upriver cauche ball..... lb.	.111 - .12
Plantation First latex crepe..... lb.	.14 -
Ribbed smoked sheets..... lb.	.12 - .121
Brown crepe, thin, clean..... lb.	.15 -
Amber crepe No. 1..... lb.	.17 -

Oils

VEGETABLE

The following prices are f.o.b. New York for earload lots.

Castor oil, No. 3, in bbls..... lb.	\$0 081 - \$0 09
Castor oil, AA, in bbls..... lb.	.10 - .101
China wood oil, in bbls. (f.o.b. Pac coast)..... lb.	.12 - .121
Cocanut oil, Ceylon grade, in bbls..... lb.	.10 - .101
Cocanut oil, Cochiti grade, in bbls..... lb.	.101 - .11
Corn oil, crude, in bbls..... lb.	.08 - .081
Cottonseed oil, crude (f. o. b. mill)..... lb.	.071 - .071
Cottonseed oil, summer yellow..... lb.	.091 - .091
Cottonseed oil, winter yellow..... lb.	.091 - .091
Linseed oil, raw, ear lots (domestic)..... gal.	.77 - .78
Linseed oil, raw, tank cars (domestic)..... gal.	.71 - .72
Linseed oil, 5-bbl lots (domestic)..... gal.	.75 - .80

Olive oil, Denatured.....	gal.	\$1.30	—	\$1.40
Palm, Lagos.....	lb.	.06	—	.06½
Palm, Niger.....	lb.	.05	—	.05½
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.07	—	.07½
Peanut oil, refined, in bbls.....	lb.	.10	—	.10½
Rapeseed oil, refined in bbls.....	gal.	.90	—	.92
Rapeseed oil, blown, in bbls.....	gal.	.94	—	.95
Soya bean oil (Manchurian), in bbls. N. Y.....	lb.	.08	—	
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.06½	—	

FISH

Light pressed menhaden.....	gal.	\$0.42	—	
Yellow bleached menhaden.....	gal.	.44	—	
White bleached menhaden.....	gal.	.46	—	
Blown menhaden.....	gal.	.50	—	

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.....	net ton	\$24.00	—	30.00
Barytes, ground, off color, f.o.b. Kings Creek.....	net ton	22.00	—	26.00
Barytes, crude, 88% @ 94% ba., Kings Creek.....	net ton	10.00	—	12.00
Barytes, floated, f.o.b. St. Louis.....	net ton	26.50	—	28.00
Barytes, crude, first grade, Missouri.....	net ton	7.00	—	
Blanc fixe, dry.....	lb.	.04½	—	.04½
Blanc fixe, pulp.....	net ton	45.00	—	55.00
Casein.....	lb.	.06½	—	.07½
Chalk, domestic, extra light.....	lb.	.04½	—	.05
Chalk, domestic, light.....	lb.	.04	—	.04½
Chalk, domestic, heavy.....	lb.	.03½	—	.04
Chalk, English, extra light.....	lb.	.04	—	.05
Chalk, English, light.....	lb.	.04½	—	.05
Chalk, English, dense.....	lb.	.04	—	.04½
China clay (kaolin) crude, f.o.b. mines, Georgia.....	net ton	8.00	—	10.00
China clay (kaolin) washed, f.o.b. Georgia.....	net ton	12.00	—	15.00
China clay (kaolin) powdered, f.o.b. Georgia.....	net ton	18.00	—	22.00
China clay (kaolin) crude f.o.b. Virginia points.....	net ton	8.00	—	12.00
China clay (kaolin) ground, f.o.b. Virginia points.....	net ton	15.00	—	25.00
China clay (kaolin), imported, lump.....	net ton	12.00	—	20.00
China clay (kaolin), imported, powdered.....	net ton	20.00	—	25.00
Feldspar, crude, f.o.b. Maryland and North Carolina points.....	gross ton	8.00	—	14.00
Feldspar, crude, f.o.b. Maine.....	net ton	7.50	—	10.00
Feldspar, ground, f.o.b. Maine.....	net ton	21.00	—	23.00
Feldspar, ground, f.o.b. North Carolina.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. N. Y. State.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. Baltimore.....	net ton	27.00	—	30.00
Fullers earth, f.o.b. Mines.....	net ton	16.00	—	17.00
Fullers earth, granular, f.o.b. Pa.....	net ton	15.00	—	18.00
Fullers earth, powdered, f.o.b. Fla.....	net ton	18.00	—	
Fullers earth, imported, powdered.....	net ton	24.00	—	27.00
Graphite, Ceylon lump, first quality.....	lb.	.07½	—	.08
Graphite, Ceylon chip.....	lb.	.06	—	.06½
Graphite, high grade amorphous crude.....	lb.	.02½	—	.03
Pumice stone, imported, lump.....	lb.	.04	—	.50
Pumice stone, domestic lump.....	lb.	.05	—	.05½
Pumice stone, ground.....	lb.	.06	—	.07
Quartz (acid tower) first to head, f.o.b. Baltimore.....	net ton		—	10.00
Quartz (acid tower) 1½ @ 2 in., f.o.b. Baltimore.....	net ton		—	14.00
Quartz (acid tower) rice, f.o.b. Baltimore.....	net ton		—	17.00
Quartz, lump, f.o.b. North Carolina.....	net ton	5.00	—	7.50
Shellac, orange fine.....	lb.	.58	—	.60
Shellac, orange superfine.....	lb.	.73	—	.74
Shellac, A. C. garnet.....	lb.	.46	—	.47
Shellac, T. N.....	lb.	.47	—	.48
Soapstone.....	ton	12.00	—	15.00
Sodium chloride.....	long ton	12.50	—	13.00
Talc, paper-making grades, f.o.b. Vermont.....	ton	11.00	—	20.00
Talc, roofing grades, f.o.b. Vermont.....	ton	8.50	—	13.00
Talc, rubber grades, f.o.b. Vermont.....	ton	11.00	—	18.00
Talc, powdered, Southern, f.o.b. cars.....	ton	10.00	—	14.00
Talc, imported.....	ton	30.00	—	40.00
Talc, California talcum powder grade.....	ton	18.00	—	40.00

Refractories

Bauxite brick, 56% Al, f.o.b. Pittsburgh.....	per ton	\$37.50-40.00		
Carborundum refractory brick, 9-in.	1,000	1,250.00		
Chrome brick, f.o.b. Eastern shipping points.....	net ton	60		
Chrome cement, 40-45% Cr ₂ O ₃	net ton	30-32		
Chrome cement, 40-45% Cr ₂ O ₃ , sacks, in car lots, f.o.b. Eastern shipping points.....	net ton	33-35		
Fireclay brick, 1st quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	36-40		
Fireclay brick, 2nd quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	30-35		
Magnesite brick, 9-in. straight.....	net ton	70		
Magnesite brick, 9-in. arches, wedges and keys.....	net ton	77		
Magnesite brick, soaps and splits.....	net ton	98		
Silica brick, 9-in. sizes, f.o.b. Chicago district.....	1,000	42-45		
Silica brick, 9-in. sizes, f.o.b. Birmingham district.....	1,000	46-50		
Silica brick, 9-in. sizes, f.o.b. Mt. Union, Pa.....	1,000	35-38		

Ferro-Alloys

All f.o.b. Works

Ferro-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.....	net ton	\$200.00	—	\$225.00
Ferrochrome per lb. of Cr. contained, 6-8% carbon, earlots.....	lb.	.14	—	
Ferrochrome, per lb. of Cr. contained, 4-6% carbon, earlots.....	lb.	.15	—	
Ferromanganese, 76-80% Mn, domestic.....	gross ton	70.00	—	
Ferromanganese, 76-80% Mn, English.....	gross ton	70.00	—	
Spiegeleisen, 18-22% Mn.....	gross ton	27.00	—	28.00
Ferromolybdenum, 50-60% Mo, per lb. of Mo.....	lb.	2.50	—	
Ferrosilicon, 10-15%.....	gross ton	40.00	—	42.00
Ferrosilicon, 50%.....	gross ton	65.00	—	68.00
Ferrosilicon, 75%.....	gross ton	135.00	—	138.00
Ferrotungsten, 70-80%, per lb. of contained W.....	lb.	.45	—	.50
Ferroumadium, 35-50% of U, per lb. of U content.....	lb.	6.00	—	
Ferrovandium, 30-40% of U, per lb. of contained V.....	lb.	4.50	—	5.00

Ores and Semi-finished Products

All f.o.b. New York, Unless Otherwise Stated

Bauxite, 52% Al content.....	gross ton	\$8.00	—	\$10.00
Chrome ore, Calif. concentrates, 50% min. Cr ₂ O ₃	unit	.30	—	.33
Chrome ore, 50% Cr ₂ O ₃ , f.o.b. Atlantic seaboard.....	unit	30	—	33
Coke, foundry, f.o.b. ovens.....	net ton	4.00	—	4.50
Coke, furnace, f.o.b. ovens.....	net ton	2.75	—	3.00
Coke, petroleum, refinery, Atlantic seaboard.....	net ton	14.00	—	15.00
Fluorspar, lump, f.o.b. mines, New Mexico.....	net ton	12.50	—	
Fluorspar, standard, domestic washed gravel Kentucky and Illinois mines.....	net ton	20.00	—	
Ilmenite, 52% TiO ₂ , per lb. ore.....	lb.	.01½	—	.01½
Manganese ore, 50% Mn, c.i.f. Atlantic seaport.....	unit	.21	—	
Manganese ore, chemical (MnO ₂).....	gross ton	50.00	—	55.00
Molybdenite, 85% MoS ₂ , per lb. of MoS ₂ , N. Y.....	lb.	.55	—	.60
Monazite, per unit of ThO ₂ , c.i.f., Atlantic seaport.....	unit	30.00	—	
Pyrites, Spanish, fines, c.i.f., Atlantic seaport.....	unit	.14	—	.14
Pyrites, Spanish, furnace size, c.i.f. Atlantic seaport.....	unit	.14	—	.14
Pyrites, domestic, fines, f.o.b. mines, Ga.....	unit	.12	—	.13
Rutile, 95% TiO ₂ per lb. ore.....	lb.	.15	—	
Tungsten, scheelite, 60% WO ₃ and over, per unit of WO ₃ (nominal).....	unit	2.75	—	3.00
Tungsten, Wolframite, 60% WO ₃ and over, per unit of WO ₃ , N. Y. C.....	unit	3.00	—	3.25
Uranium ore (carnotite) per lb. of U ₃ O ₈	lb.	1.50	—	2.50
Uranium oxide, 96% per lb. contained U ₃ O ₈	lb.	2.25	—	2.50
Vanadium pentoxide, 99%.....	lb.	12.00	—	14.00
Vanadium ore, per lb. of V ₂ O ₅ contained.....	lb.	1.00	—	
Zircon, washed, iron free.....	lb.	.03	—	

Non-Ferrous Metals

New York Markets

	Cents per Lb.
Copper, electrolytic.....	12.25 @ 12.50
Aluminum, 98 to 99 per cent.....	24.5 @ 25
Antimony, wholesale lots, Chinese and Japanese.....	4½
Nickel, ordinary (ingot).....	41.00
Nickel, electrolytic.....	44.00
Monel metal, spot and blocks.....	35.00
Monel metal, ingots.....	38.00
Monel metal, sheet bars.....	40.00
Tin, 5-ton lots, Straits.....	26.50
Lead, New York, spot.....	4.35-4.40
Lead, E. St. Louis, spot.....	4.20-4.25
Zinc, spot, New York.....	4.50-4.55
Zinc, spot, E. St. Louis.....	4.15-4.20

OTHER METALS

Silver (commercial).....	oz.	\$0.59½
Cadmium.....	lb.	1.00-1.25
Bismuth (500 lb. lots).....	lb.	1.50 @ 1.55
Cobalt.....	lb.	3.00 @ 3.25
Magnesium (f.o.b. Philadelphia).....	lb.	1.25
Platinum.....	oz.	72.00 @ 75.00
Iridium.....	oz.	160.00 @ 180.00
Palladium.....	oz.	60.00-65.00
Mercury.....	75 lb.	44.00-45.00

FINISHED METAL PRODUCTS

	Warehouse Price Cents per Lb.
Copper sheets, hot rolled.....	20 75-21 25
Copper bottoms.....	28 25-28 75
Copper rods.....	19 75-20.00
High brass wire.....	16 75
High brass rods.....	13 75
Low brass wire.....	18 25
Low brass rods.....	18 25
Brazed brass tubing.....	27.00
Brazed bronze tubing.....	31.75
Seamless copper tubing.....	21.00
Seamless high brass tubing.....	18.50

OLD METALS—The following are the dealers' purchasing prices in cents per pound:

	New York Current	Cleveland	Chicago

*Add 15c per 100 lb. for trucking to Jersey City and 10c for delivery in New York and Brooklyn

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

GADSDEN—The Stringer Brothers Foundry Co., 109 North Dearborn St., Chicago, Ill., manufacturer of brass and iron goods, has commenced the construction of a new plant at Gadsden, to be operated as a branch works. An extensive iron and brass foundry will be installed. It is planned to inaugurate operations at an early date. Charles C. Stringer is president.

GADSDEN—The Gadsden Clay Products Co., recently organized, will operate a local plant for the manufacture of building tile and other burned clay products. The initial works will be enlarged at a later date and new machinery installed. Robert Riley is president and Gordon Hood, treasurer.

California

OAKLAND—The Moore Shipbuilding Co., foot of Adeline St., has filed plans for the erection of a new 1-story brass foundry at its plant.

Delaware

WILMINGTON—The Atlas Powder Co., du Pont Bldg., is taking bids for the construction of a new 1-story experimental laboratory at Gray St., and Lancaster Ave., 60x80 ft.

District of Columbia

WASHINGTON—A. L. Flint, general purchasing officer, the Panama Canal, will receive bids until 10:30 a.m., August 3, for chemicals, lime, creosote oil, calcium chloride, varnish, linseed oil, and other materials and equipment, as set forth in Circular 1453, for Canal Zone service.

Florida

TAMPA—The United Paper Co., Atlanta, Ga., has awarded a contract to E. W. Parker, Curry Building, Tampa, for the erection of a new local plant, 100x100 ft., for the manufacture of paper specialties. It is estimated to cost about \$50,000, including machinery. N. Sargent Hamilton, Atlanta, is architect. Louis Wellhouse is president.

MADISON—The Producers' Co., manufacturer of peanut oil and kindred products, has resumed production at its local plant after a curtailment of several months duration. The company is giving employment to about 75 operatives, and plans to increase this force to 100 persons. It is proposed to operate under full time for an indefinite period.

Illinois

CHICAGO—Curt, Teich & Company, 1745 Irving Park Boulevard, manufacturer of paper specialties, has awarded a contract to Peter Hamel, 6401 South Campbell St., for the erection of a 2-story plant addition, 125x125 ft., estimated to cost about \$100,000 with machinery. Ground will be broken at an early date.

CHICAGO—The Wheeling Corrugating Co., 2547 Arthington Ave., is taking bids for the erection of a new 1-story plant addition, 80x125 ft., estimated to cost about \$40,000.

Indiana

MICHIGAN CITY—The Triangle Steel Products Co., care of T. C. Casse, 163 Washington St., has plans under way for the erection of a new 1-story and basement plant at Michigan City, 250x500 ft., estimated to cost about \$75,000 with machinery.

Louisiana

NEW ORLEANS—Fire, July 6, destroyed a portion of the Richardson chemistry building at the Tulane University, with loss estimated at about \$17,000. The structure will be rebuilt.

COLEMAN—D. C. Nelson, Fort Worth, Tex., and associates, are organizing a new

company to build and operate a local oil refining plant. Details and estimates of cost are being made.

NEW ORLEANS—The Marland Refining Co., Ponca City, Okla., has acquired property at St. Charles Parish, about 20 miles from New Orleans, and has plans under way for the erection of a new oil terminal plant to cost in excess of \$1,000,000, including equipment.

CARGAS—The United Oil & Natural Gas Products Co., Monroe, La., is planning for the erection of a new local plant for the manufacture of gasoline to cost about \$30,000.

Maryland

BALTIMORE—Fire, July 9, destroyed the plant of the Meadowbrook Dye Works, Caton Ave., with loss estimated at about \$30,000. It is said that the plant will be rebuilt.

Mississippi

MERIDAN—The Texas Oil Co. and the Gulf Refining Co. are planning for the rebuilding of the portions of their local oil plants, destroyed by fire, June 28, with loss estimated in excess of \$100,000, including equipment.

Missouri

KANSAS CITY—The Central Chemical & Supply Co., has leased a local building, 3-story, totaling about 20,000 sq. ft. of space, for the establishment of a new works for the manufacture of paints and kindred products. Machinery will be installed at an early date. C. H. Hughes is head.

CLINTON—The Terrill Tire & Rubber Co., 1512 McGee St., Kansas City, Mo., has awarded a contract to Frank Woodruff, Clinton, for the erection of its proposed new local plant, to be 2-story and basement, 90x150 ft., and estimated to cost about \$32,000. A. C. Terrill is president.

ST. LOUIS—The Fleischmann Yeast Co., 1535 Market St., has filed plans for the erection of its proposed local plant on Forest Park Boulevard, 1-story, 75x170 ft., estimated to cost about \$50,000. H. K. Stephens is local manager.

New Jersey

NEWARK—The United Butchers' Fat Rendering Co., Robert H. Bayerl, 302 Jackson Ave., Jersey City, N. J., president, is having plans prepared by David M. Ach, 1 Madison Ave., New York, architect, for its proposed new rendering plant on Doremus Ave., Newark, for fertilizer, glue, tallow and affiliated manufacture. It will be 2-story and is estimated to cost about \$50,000. Bids will be taken at an early date.

FLORENCE—The Florence Pipe Foundry & Machine Co., has awarded a contract to the Austin Co., Bulletin Bldg., Philadelphia, Pa., for the erection of a new 1-story building at its plant, 40x100 ft., estimated to cost about \$25,000. C. L. Reeves is head.

New York

BUFFALO—Fire, July 10, destroyed a portion of the plant of the Archer-Daniels Linseed Co., Hamburg Turnpike, with loss estimated at about \$50,000, including equipment.

BUFFALO—The Towns Paint Co., Inc., has established a new plant at 127 Erie St. and has arranged for immediate manufacture, with production to include paints, varnishes, etc. Joseph C. Alonzo, formerly chief chemist and assistant superintendent of the Campbell Paint & Varnish Co., St. Louis, Mo., will be in charge of operations.

NIAGARA FALLS—The Sinclair Consolidated Oil Corp., 120 Broadway, New York, is reported to have purchased a local site, comprising a large acreage, for the erection of a new oil refining plant, estimated to cost in excess of \$2,500,000 with machinery.

NEW YORK—The Tide Water Oil Co., 11 Broadway, has taken over the property of the Guffey-Gillespie Oil Co., including refineries and oil plants, and will operate the business in the future. The name of

the company will be changed to the Tide Oil Co.

LONG ISLAND CITY—The Textile Alliance, New York, has leased for a long term, the factory building now being erected on a site 95x190 ft., on Van Alst Avenue near Harris Ave., Long Island City, for dye operations, including departments for production, rehandling, reconditioning, etc.

North Carolina

RUTHERFORDTON—The Schenck Gold Mining Co., recently incorporated with a capital of \$250,000, is planning for the development of gold properties in this section, recently acquired. The tract totals about 225 acres, and will be provided with a complete mining and operating plant. L. A. Warrick, is president and general manager.

Ohio

CORTLAND—The Quinby Magnesia Co., 306 Federal Bldg., Youngstown, Ohio, has completed foundation work for a new plant at Cortland, to be 2-story, 100x50 ft., and will commence the erection of superstructure at an early date. J. C. Quinby is president and mechanical engineer for the work.

CLEVELAND—The Sterling Brass Co., 4619-12 St. Clair Ave., has rejected bids recently received for the erection of its proposed new brass foundry at St. Catherine and East 93 Streets. Revised plans will be drawn and new bids asked. The plant, with machine shop, will be 2-story, 145x200 ft., and is estimated to cost about \$100,000. S. L. Weil is head.

Pennsylvania

CHESTER—The American Chemical & Sugar Machinery Co., Colonial Trust Building, Philadelphia, Pa., has acquired the local plant of the Harrison Chemical Co., and will commence the erection of superstructure for a new plant. Machinery will be installed at an early date. It is proposed to give employment to about 200 operatives. The plant has been shut-down for some time past, and at time of erection was used as a foundry.

PHILADELPHIA—Samuel McDowell, manufacturer of chemicals, has acquired a local plant, formerly occupied by the Providence Worsted Mills, for a new factory. Equipment will be installed at once, and the works operated as a branch of the present chemical plant.

South Carolina

ORANGEBURG—The Common Council is considering the erection of a new municipal gas plant, estimated to cost about \$100,000. Edward Hawes, engineer, City Bldg., is preparing preliminary plans.

Texas

WACO—W. A. Rogers, Houston, Tex., and associates, have acquired the local oil refinery of the Ryan & Fisher Refinery & Production Co. Plans are under way to increase the capacity of the plant from 500 to 1,000 bbl. a day.

CISCO—The Cisco Clay & Coal Co. is considering the erection of a new local plant for the manufacture of brick and tile. At a later date an extension will be constructed to be devoted to the manufacture of paving brick and other burned clay products. C. B. Bush is president.

Utah

SALT LAKE CITY—Fire July 5 destroyed a portion of the plant of Acme White Lead & Color Works, 255 Edison St. Plans for rebuilding are said to be under way.

West Virginia

HUNTINGTON—The Melick Petroleum & Coal Co., recently organized with a capital of \$5,000,000, is planning for the erection of a new oil-refining plant to cost close to \$1,000,000 with equipment. David L. Melick is president and general manager.

Wisconsin

NEENAH—The Valley Paper Mills, 5 Caswell Block, are having plans prepared by Edward A. Wettengel, 578 Pierce Ave., Appleton, Wis., for the erection of their proposed new local paper manufacturing plant, estimated to cost close to \$500,000 with machinery. A. C. Ehlmann is president.

Quebec

KIPPEWA—The Riordan Paper Co. is planning for the rebuilding of the portion of its local mill, destroyed by fire, June 22, with loss reported at about \$25,000.

New Companies

THE PUBLIC OIL Co., Room 720, 10 South LaSalle St., Chicago, Ill., has been incorporated with a capital of \$50,000, to manufacture oil products. The incorporators are Paul Vitek and George Kucharik.

THE PINNACLE PAINT Co., Sault Ste. Marie, Mich., has been incorporated with a capital of \$15,000, to manufacture paints, oils, varnishes, etc. The incorporators are Pearson S. Conrad Jr., Campbell E. Lyons and Walter H. McKinney, Sault Ste. Marie.

THE KEMOSHYNE PRODUCTS, INC., Camden, N. J., has been incorporated with a capital of 4,000 shares of stock, no par value, to manufacture polishes, oils and kindred products. The incorporators are Thomas B. Kenworthy, M. G. Black and Delbert S. Bacon. The company is represented by Walter R. Carroll, Fourth and Market Streets, Camden.

THE PLYMOUTH CHEMICAL Co., New York, N. Y., has been incorporated with a capital of \$20,000, to manufacture chemical and chemical by-products. The incorporators are E. Stark, F. F. Jones and M. Rothman. The company is represented by J. D. Campbell, 200 Fifth Ave.

THE COMMERCIAL TALC Co., Lincoln, R. I., has been incorporated with a capital of \$300,000, to operate talc properties and talc refining plants. The incorporators are George R. Price, John P. Sheern and George Messenger, 650 Broad St., Providence, R. I.

THE MOUNTAIN CITY CHEMICAL Co., Fairmont, W. Va., has been incorporated with a capital of \$100,000, to manufacture chemicals and chemical by-products. The incorporators are Brooks S. Hutchison and J. V. Abbott, Fairmont.

THE ALLAN MFG. Co., St. Paul, Minn., has been incorporated with a capital of \$50,000, to manufacture soaps and kindred products. The incorporators are E. M. Hagan, H. K. Null and George W. Allan, St. Paul.

C. H. FINGERHOOD, INC., New York, N. Y., has been incorporated with a capital of \$20,000, to manufacture industrial alcohol and affiliated products. The incorporators are E. Nelson, F. and C. H. Fingerhood, 911 Southern Boulevard.

THE SAMOSET OIL Co., Boston, Mass., has been incorporated with a capital of \$300,000, to manufacture refined oil products. Charles M. Bergul is president, and Michael A. Dunn, 11 High St., Framingham, Mass., treasurer.

THE EASTERN PETROLEUM CORP., New York, N. Y., has been incorporated with a capital of \$180,000, to manufacture petroleum products. The incorporators are G. A. Ross, F. C. Sumner and J. W. Seemans. The company is represented by J. R. Meany, 205 West 91st St.

THE PARKO MFG. Co., Rochester, N. Y., has been incorporated with a capital of \$250,000, to manufacture soaps, polishing compounds, etc. The incorporators are J. G. Rispor, L. C. Graves and C. F. Wray. The company is represented by Stull Bros., attorneys, Rochester.

THE BRONSON CHEMICAL Co., 234 1/2 Broad St., Providence, R. I., has filed notice of organization to manufacture chemical products. The company is headed by Moody D. Holmes.

THE CENTRAL OIL & GREASE Co., INC., Williamsport, Pa., has been incorporated with a capital of \$50,000, to manufacture oils, greases, compounds, etc. Frank W. Kosh, South Williamsport, Pa., is treasurer.

THE PYRO COLOR CORP., Richmond, Va., has been incorporated with a capital of \$1,250,000, to manufacture colors, chemicals, dyes, etc. The incorporators are Lee B. Horey and W. C. Faulkner, Richmond.

THE KENTUCKY MIDLAND PIPE LINE AND REFINING Co., New York, N. Y., has been incorporated under Delaware laws with a capital of \$5,000,000, to manufacture refined oil products. The company is represented by Arthur W. Britton, 65 Cedar St.

THE HARRISVILLE ORE & STEEL CORP., New York, N. Y., has been incorporated with a capital of \$500,000, to operate iron ore properties, and manufacture steel and other metal products. The incorporators are H. G. Conway, E. G. Kerr and M. F. Dudek. The company is represented by Penslee & Compton, 501 Fifth Ave.

THE ORANGEVILLE BRICK & SHALE PRODUCTS Co., Orangeville, Ohio, has been incorporated under Pennsylvania laws with a capital of \$100,000, to manufacture brick and other burned clay products. E. W. Hyde, Orangeville, is treasurer.

THE MODERN CHEMICAL Co., Chelsea, Mass., has been incorporated with a capital

of \$10,000, to manufacture chemicals, and chemical byproducts. Samuel Leabman is president, and David Glassman, 99 Shurtleff St., Chelsea, is treasurer.

THE WEBACO OIL Co., Webster (Monroe Co.), N. Y., has been incorporated with a capital of \$100,000, to manufacture refined oil products. The incorporators are G. B. and E. Kittelberger, and C. E. Sutter, Webster.

THE FLORIMER CHEMICAL CORP., New York, N. Y., has been incorporated with a capital of \$20,000, to manufacture chemicals and chemical byproducts. The incorporators are M. Levin, P. J. Rassler and T. T. Schwalbe. The company is represented by A. J. Halprim, 41 Park Row.

THE CONVERSE TIRE Co., Malden, Mass., has been incorporated with a capital of \$1,000,000, to manufacture automobile tires and mechanical rubber goods. Marquise M. Converse is president; Hugh Bullock, 392 Pearl St., Malden is treasurer.

THE DUNCAN LUBRICANT OIL WORKS, INC., Duncan, Okla., has been incorporated with a capital of \$50,000, to manufacture lubricating oils, compounds, etc. The incorporators are J. R. Frensley, and Roy K. Wilson, Duncan.

THE MISSOURI VALLEY OIL Co., Sioux City, Ia., has been incorporated with a capital of \$100,000, to manufacture petroleum products. The incorporators are M. P. Summers, C. E. Naughton and C. T. Mauller, Sioux City.

THE ARGONNE CHEMICAL AND DRUG Co., New York, N. Y., has been incorporated with a capital of \$50,000, to manufacture chemicals, chemical byproducts, drug compounds, etc. The incorporators are J. and P. Dondero and C. McLester. The company is represented by Ryan, Heffernan & Dowan, 25 West 45 St.

THE STANDARD CHEMICAL CORP., 723 Calvert Bldg., Baltimore, Md., has been incorporated with a capital of \$300,000, to manufacture chemical specialties. The incorporators are Luther E. Mellen, Jacob L. Rosenfield and J. Charles Fagan.

THE PENN RUBBER PRODUCTS CORP., Philadelphia, Pa., has been incorporated with a capital of \$500,000, to manufacture rubber specialties. The company is represented by F. R. Hansell, Land Title Bldg.

MASON & URNER, INC., Newark, N. J., has been incorporated with a capital of \$125,000, to manufacture refined oil products. The incorporators are Thomas T. Gray, Frank A. Urner and Frank B. Mason, 961 Frelinghuysen Ave.

THE SAMOLINE CORP., Room 2134, 6 North Clark St., Chicago, Ill., has been incorporated with a capital of \$350,000, to manufacture paints, oils, varnishes and kindred products. The incorporators are Samuel R. Olmsted, Martin Skarie and Thomas A. Weldon.

THE LIBERTY PETROLEUM CORP., 1119 Fidelity Building, Baltimore, Md., has been incorporated with a capital of \$2,500,000, to manufacture petroleum products and hydrocarbons. The incorporators are Edward M. and E. H. Hammond and Harry E. Karr.

THE LA PREME IVORY NOVELTY Co., Bloomfield, N. J., has been incorporated with a capital of \$25,000, to manufacture celluloid and other composition products. The incorporators are Richard Webster and G. A. Breite, Passaic Ave. and Center St.

THE CORTLAND DRUG & CHEMICAL CORP., New York, N. Y., has been incorporated with a capital of \$100,000, to manufacture chemicals, drug compounds, etc. The incorporators are R. Cairone, W. S. Berman and H. Herzog. The company is represented by C. Firestone, 299 Broadway.

THE NITRO FOUNDRY Co., Nitro, W. Va., has been incorporated with a capital of \$50,000, to manufacture iron, steel and other metal castings. The incorporators are Ralph Matthews, M. S. Aldrich and W. A. O'Neill.

THE PROCESS PAPER Co., Lockport, N. Y., has been incorporated with a capital of \$50,000, to manufacture paper products. The incorporators are G. E. Greene, G. F. McEndoe and G. C. Lewis, Lockport.

THE NOVO LABORATORIES, INC., Perth Amboy, N. J., has been incorporated with a capital of \$125,000, to manufacture chemicals and chemical byproducts. The incorporators are Samuel Cutler, M. A. Fenwick and Boris I. Rabiner, 651 Catherine Street, Perth Amboy.

THE LINCOLN CONNER CORP., New York, N. Y., has been incorporated with a capital of \$60,000, to manufacture inks, dyes, chemicals and affiliated products. The incorporators are D. Greenebaum and L. and B. F. Conner. The company is represented by S. Wasserman, 51 Chambers Street.

THE WESTFIELD CHEMICAL CORP., New York City, has been incorporated with a capital of \$25,000 to manufacture chemicals and affiliated products. The incorporators are G. Giofre, C. Cacetta and F. A. Brune, 395 B'way.

THE PURITY CHEMICAL PRODUCTS Co., Jeffersonville, Ind., has been incorporated with a capital of \$5,000 to manufacture chemicals and chemical byproducts. The incorporators are J. B. Doherty, G. H. Haas and D. C. Peyton, Jeffersonville.

Capital Increases, etc.

THE WISCONSIN LIME & CEMENT Co., 133 West Washington St., Chicago, Ill., manufacturer of cement, lime products, etc., has filed notice of increase in capital from \$200,000, to \$1,000,000.

THE RICH STEEL PRODUCTS Co., Battle Creek, Mich., is arranging for a decrease in its capital from \$250,000 to \$100,000.

THE SUPERIOR FLUOR SPAR Co., Evansville, Ind., has filed notice of dissolution under state laws.

L. MUNDET & SON, INC., Ferris St., Brooklyn, N. Y., manufacturer of cork products, has filed notice of increase in capital from \$350,000 to \$2,500,000.

THE CUMBERLAND HYDRAULIC CEMENT & MFG. Co., Cumberland, Md., has filed notice of increase in capital from \$200,000 to \$450,000.

THE COLE CHEMICAL Co., 406 Market St., St. Louis, Mo., has filed notice of increase in capital from \$50,000 to \$1,000,000.

THE DETROIT COPPER & BRASS ROLLING MILLS INC., North Jefferson Street, Chicago, Ill., has filed notice of dissolution under state laws.

THE ELGIN RUBBER ACE Co., Elgin, Ill., has filed notice of increase in capital from \$150,000 to \$500,000.

THE KINZIE RUBBER & MFG. Co., 1514 West Kinzie St., Chicago, Ill., has filed notice of increase in capital from \$350,000 to \$412,500.

THE PACIFIC-TEXAS PETROLEUM Co., Mineral Springs, Tex., has filed notice of increase in capital from \$1,000,000 to \$4,000,000.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY's summer meeting is being held at Canton, Alliance, Sebring and East Liverpool, Ohio, July 25 to 27. Headquarters are at the Hotel Courtland, Canton, Ohio.

AMERICAN CHEMICAL SOCIETY, THE SOCIETY OF CHEMICAL INDUSTRY and the American Section of the latter society will hold a joint meeting in New York, Sept. 6 to 10.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in Lake Placid, N. Y., Sept. 29 and 30, and Oct. 1.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its fall meeting at Wilkes-Barre, Pa., Sept. 12 to 17.

AMERICAN MINING CONGRESS AND NATIONAL EXPOSITION OF MINES AND MINING EQUIPMENT will hold its twenty-fourth annual convention in the Coliseum, Chicago, Oct. 17 to 22.

AMERICAN SOCIETY FOR STEEL TREATING will hold its third annual convention and exhibition Sept. 19 to 24 at Indianapolis.

THE NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SEVENTH) will be held during the week of Sept. 12 in the Eighth Coast Artillery Armory, New York City.

NEW JERSEY CHEMICAL SOCIETY has discontinued meetings for the summer and will resume them in October.

SOCIETY OF CHEMICAL INDUSTRY (BRITISH) at the invitation of the Montreal section will hold its annual meeting in Montreal and other Canadian cities during the week of Aug. 29, 1921. Details will be printed in this magazine from time to time.

SOCIETY OF INDUSTRIAL ENGINEERS will hold its fall meeting at Springfield, Mass., Oct. 5 to 7.

TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its fall convention with the American Pulp and Paper Mill Superintendents' Association, at Washington, Philadelphia, Spring Grove, York, York Haven, Pa., and Wilmington, Del., Oct. 18 to 20.

Number 5

A Leaf Out Of the Past

THE London *Times* lately told a few things about the Royal Institution of Great Britain which are worth remembering—and worth pondering over as well. It was founded by a few Fellows of the Royal Society in 1799 of whom Count RUMFORD provided the initial funds. Its purpose was to “diffuse knowledge of useful mechanical improvements” and to “teach the application of science to the useful purposes of life.” It was to be popular and practical enough to satisfy anybody. But its administrators soon discovered that the only way to be practical in things scientific is to engage in research. The reason should be patent to everyone, although unfortunately it is not. Science is not static; it does not stand still; it is dynamic; it is pressing forward and according to Dr. SARTON it presses forward in the ratio of human development. The history of science he says is the history of human progress and he gives a galaxy of evidence to prove his thesis. If then we are to “diffuse” or “teach” this moving thing we cannot stand still ourselves. If we do, it will move away from us. Our only method therefore is to get aboard the research van and to move along with it. Otherwise we shall teach something that has gone on and left us behind.

On the other hand, if we merely set somebody to work in a laboratory and call it the prosecution of research we are not of necessity accomplishing anything. We are doomed to failure unless we have wisdom—and use it. The Governors of the Royal Institution proved themselves to be of the elect in this respect. By July, 1801, they had established THOMAS YOUNG as the first resident professor, who as the *Times* puts it, “was the father of all our knowledge of color vision and of the properties of the lens of the human eye, the discoverer of ‘interference’ and the first to define ‘energy.’” The statement may be a little broad, but let’s pass it on without discussion. The same year they engaged HUMPHRY DAVY at a salary of 100 pounds a year, a room, coal and candles. In return for this he gave popular lectures which became the talk of London, and his contributions have become classic. He was succeeded by MICHAEL FARADAY, whose name is writ high in the heavens of science, and the present resident professor is Sir JAMES DEWAR. The mere mention of these names conjures up the living soul of science today.

The only recorded static aid to the Royal Institution was a Civil List pension of £300 annually to FARADAY for a few years. The whole cost of the Royal Institution during the entire nineteenth century, including professors, attendants, the maintenance of laboratories and the purchase of apparatus and materials, was £100,620, or a little over £1,000 a year. Gifts and

donations have been few; the revenue to support the institution has been almost wholly derived from admission fees paid by the public to hear the lectures.

What a record this is! No begging, no pulling and stripping of the legs of millionaires, nobody getting personally rich out of it and nobody made poor, and yet what a benefit to all humanity! FARADAY was so interested in his work that he refused a fortune for himself in order to provide wealth and happiness for generations then unborn. Sometimes it seems as though in some respects we hadn’t kept up with those memories of grace that came over from the eighteenth century, lasted into the nineteenth for a while, and then, somehow, went into eclipse.

Prohibition and Industrial Alcohol

WEBSTER defines a fanatic as “a person affected by excessive enthusiasm; one who indulges in wild and extravagant notions; a visionary zealot.” A zealot, according to the same authority, is “one who engages warmly in any cause and pursues his subject with earnestness and ardor.” Can it be possible that with rare prescience Mr. WEBSTER was giving us a character delineation of Mr. VOLSTEAD? We infer as much from comments in the daily press and from the laws for prohibition enforcement proposed by the honorable Congressman.

The exact wording of the Eighteenth Amendment escapes us for the moment, but we are under the impression that it prohibits the manufacture and sale of alcoholic liquor for *beverage* purposes. No mention is made of industrial or medicinal purposes, and as far as we are aware there was no intention to affect those legitimate uses of alcohol. It is not surprising, therefore, that in the recent debate on Mr. VOLSTEAD’S supplementary bill for prohibition enforcement several Senators reminded their colleagues that industrial and medicinal uses of alcohol are outside the pale of the Eighteenth Amendment; that there is a large and legitimate industrial alcohol industry quite apart from the business that is prohibited. In support of this contention it is worth noting that the failure of the British Government to give its dye industry duty-free alcohol is ascribed by the *Chemical Age*, London, as one of the two major causes contributing to the failure of the early efforts to establish a dye industry in England. Germany, on the other hand, recognizing the importance of industrial alcohol, fostered the industry by removing restrictions and handicaps and otherwise built up the greatest coal-tar industry the world has ever seen. If Mr. VOLSTEAD can become less obsessed with the iniquity of “booze” and more impressed with the essential and legitimate uses of alcohol, numerous and varied industries will breathe more freely.

Business Revival

And Our Export Trade

IN THESE days when foreign trade and the tariff figure so prominently in our schemes for business revival, it is perhaps time to take an inventory and pass judgment on the relative importance of these factors. Foreign trade has been emphasized to such an extent of late that we are apt to lose sight of the fact that even in the balmiest years when exports were at their peak, they amounted to less than eight per cent of the total sales of the country. We often fail to realize that over ninety per cent of business as a whole was done in the domestic market.

The resumption of exports must depend, to a large extent, upon the foreign buyer's ability to pay us for our goods. If the restoration of normal business in this country, however, is to await the financial rehabilitation of Europe, then our return to prosperity promises to be a slow and difficult process. It is best that our efforts at business revival be diverted toward the home market, wherein lies the greater opportunity.

The Government can assist in this process mainly by the enactment of proper tariff and taxation measures. It is extremely difficult for the layman to see how the tariff is going to restrict imports and at the same time build up our export trade. We have hopes, however, that the new law will be so framed that the home market will be reserved for the domestic manufacturer, but that this will be accomplished without prohibiting fair competition from abroad. Europe must pay her obligations in goods, but obviously those goods must be such as to affect least seriously our own industries. Taxation enters into our calculations somewhat less directly, for taxes are seldom so oppressive as to have material effect on our purchasing power. It is generally admitted, on the other hand, that the present distribution of taxes has retarded rather than encouraged the investment of capital in necessary building and development.

Industry's chief contribution to the reviving process consists in the adjustment to lower prices by means of higher efficiency and hard work. This adjustment is inevitable and the American manufacturer must meet the situation with lower costs, which in turn mean increased efficiency.

Industry is affected in some degree by our exports and for that reason the export problem can not be dismissed completely from our consideration. In the case of many commodities, this trade, although of small volume, has an entirely disproportionate significance. A normal outflow will continue for those products for which our natural resources or our own ingenuity have placed us in a position of comparative advantage. Copper, iron and steel, cotton, meat and farm products are natural exports. We are also peculiarly adapted to export fabricated articles of large-scale production and standardized manufacture. Our foreign trade in dyes is an example of this natural development. The well-standardized articles of quantity output, such as indigo and sulphur black, are produced in excess of our requirements and are exported in large quantities. On the other hand there are many special products of secondary importance from a quantitative viewpoint which our industry is not yet producing in adequate amounts to supply even the domestic consumption.

A foreign outlet for some other products of our chemical industry is desirable and essential, but it is to be admitted that much of our war-time trade was

unnatural and its continuation can not be expected. Artificial stimulation by foreign financing and the exporting of goods on long-time credits have been proposed, but in our estimation they represent only a means of continuing our abnormal exports. Our foreign trade must be put on a safe and logical basis, but in the meantime we should not forget that our most direct path to business revival lies at our very door.

News Value or

Nuisance Value?

ON THE HOTTEST day yet there came to us a "news note" from a well-known corporation that shall be nameless because it ought to know better. Probably the Old Man does know better but is away on his vacation. The item reads as follows: "Blank Co. Distributes New Blotter. The Blank Co. are placing in the hands of their representatives for distribution a new and attractive blotter. The Blank Co. have always been strong advocates of the blotter for advertising purposes because of its usefulness, its attention value and its ability to drive home its sales message."

This is the kind of information for which our readers are supposed to hunger and thirst; to pay good money for subscriptions so that they may read it and still more good money to have their advertisement accompany it. It pains us to have anybody think so. We have a high opinion of our readers; a sense of brotherhood with them. We talk out of our hearts to them and feel that they understand, and in return they often talk straight from their hearts to us and we think we understand. We don't set up to be professional high-brows (who are those, according to Brander Matthews, whose instruction exceeds their mental capacity), but at the same time we do not worry over reducing the expression of our opinions to words of one syllable. We do not worry over the adenoids of our readers; we take it for granted that if they ever were congested they were duly removed; and we do not try to reach the feeble minded or those who are defective.

On the other hand we want news; all the news that is really news and that is worth reading and fit to print. Had the company in question developed a new product or process, different from any that is known and of such value that in our judgment our readers would be glad to know of it, we should have been glad to publish a technical article on the subject. We are not influenced by the advertising value such an article may have to the concern that produces the apparatus or product. If we think it worth while we print it, whereas if we do not think it worth while there isn't any money that can get it printed except at advertising rates and as an advertisement in the advertising section.

We do not print advertisements either as so-called "reading matter"—to fool our readers, or interspersed with it—to disturb them. Advertising is a legitimate art but it has been made the subject of serious malpractice. One of the most serious phases of this malpractice is to give it nuisance value. It consists in stealing the attention of busy men to tell them something they do not want to know. It has not a tithe of the value ascribed to it. Men with things to do and with obligations to perform are beginning to realize this. If we do not chew tobacco we do not want to be told which preparation of tobacco to chew. When we read our morning newspaper and are trying to learn what is being done with the tariff bill in Washington, we do not want to be interrupted by the information.

that the Maison de Paris is having a grand marked-down sale of lingerie. On the other hand, the women of the household may want to know about the sale but may not be interested in the tariff bill. This misplacement of news and advertising is a mistake, so far as we are concerned.

Worse than such a mix-up of understanding and underwear is the publication of news of such inane items as that a corporation has bought some blotting paper and had its name printed on it. That brings the corporation's name before our readers, but it offends them, and rightly so. It does not interest us and we don't see how it can interest anybody else.

The Steel Corporation's Quarterly Report

THE United States Steel Corporation reports \$21,892,016 as its "net earnings" in the second quarter of this year, against \$32,286,722 in the first quarter and averages of \$44,000,000 per quarter in 1920, \$83,000,000 per quarter in 1916, its best year, and \$18,000,000 per quarter in 1914, its poorest year.

Wall Street found the earnings reported for the quarter just ended higher than expected and considered them very favorable in the circumstances. Wall Street looks upon these matters from the viewpoint of returns and prospects of returns on the stock outstanding.

From the manufacturing viewpoint the angle is different. Such a thing as a direct loss from operation, or lack of operation, is conceivable. Wall Street regards "net earnings" as a positive quantity, the only question being how much they will be above zero. They could be below zero, however, the amount of money expended or the obligations incurred exceeding the amount of money received for goods or services furnished. If the Steel Corporation had not turned a wheel during the quarter the expenses would have amounted to something like \$15,000,000 or more—the "net earnings" would have been that amount below zero. This total would have been made up of taxes, rents, salaries, subsidiary company bond interest and a number of other items. Interest and sinking funds on bonds of the Steel Corporation itself, depreciation charges, etc., are met out of "net earnings."

The Steel Corporation plants were not wholly idle in the quarter, but they operated at an average of only between 35 and 40 per cent. Often a manufacturing business finds it impossible to pay expenses with a 50 per cent operation, and thus the Steel Corporation did well to have any "net earnings" at all.

The showing of the Steel Corporation is made more favorable still by another consideration, that there was a decidedly broad distribution of work among its various plants. A few small plants were closed, but by far the major portion of the productive capacity was kept in partial operation, instead of work being concentrated at a few plants. That is quite different from the policy contemplated in the great period of industrial consolidation 20 to 25 years ago. An argument of which the promoters of many consolidations were proud was that in times of stress some plants could be closed and others operated in full, while no particular secret was made of the thought that when it came time to resume work at idle plants they could be started with substantial wage reductions. This distribution of work, prompted by a desire to take care of employees as far as possible, and other influences, swelled the corporation's costs per ton in the quarter just ended far above

what they would have been with a reasonably full operation although with other conditions, such as wage rates, the same.

Conditions in the present quarter are more unfavorable than conditions in the June quarter. An average operating rate of between 35 and 40 per cent in the June quarter is followed by a rate of not over about 25 per cent at the beginning of the present quarter, and sufficient increase to strike the same quarterly average is improbable. Steel prices are already about \$6 per net ton below the average price at which shipments in the June quarter were invoiced, and the trend is still downward. At the middle of the June quarter, however, there was a wage reduction, and another, to the level now common among the independent steel producers, may occur before the end of the present quarter. A part of the Steel Corporation's earnings, of course, is derived from railroad operation and the production of cement and some other materials outside of steel.

Better Business Methods Needed

WHOLESONE advice and plain talk in palatable form characterized the address of President CHARLES H. MACDOWELL, at the recent convention of the National Fertilizer Association. Presumably his words have already reached to the uttermost parts of the fertilizer industry, but his speech could well be pondered by chemical industries other than the one to which he addressed himself. We surmise, for example, that fertilizer manufacturers are not the only ones who are ignorant of manufacturing costs or guilty of basing prices on incorrect estimates. The pitfalls left unguarded through inadequate cost-accounting are more numerous than obvious. Improvements in technology frequently find their mainspring in the cost sheet, while prudent business economy demands a thorough knowledge of those hidden and less obvious elements in cost which appear only at long intervals. Mr. MACDOWELL therefore properly took the fertilizer industry to task for ignorance of its actual costs and for the waste and inefficiency arising from lack of that knowledge.

Leadership along sound constructive lines, and not blind acquiescence to custom was another element of Mr. MACDOWELL's address. He deprecated the custom of supplying the farmer with "what he wants" in way of fertilizer instead of pointing the way to the most economical use of the most efficient fertilizers, educating the consumer to purchase on the basis of plant food units rather than cost per ton. The practice of manufacturing many brands and grades was also shown to be an important factor in increasing manufacturing costs. That it serves no useful purpose to either producer or consumer is indicated in the fact that Mr. MACDOWELL spoke of it as "all of this nonsense," and urged "a drastic elimination of brands and formulæ."

Methods of organization, relation of the parts of an organization to each other and the whole, co-ordination between sales and production managers, industrial statistics and freight rates all came in for a share of attention from Mr. MACDOWELL. In fact his speech was a wholesome industrial sermon applicable to a wider audience than he addressed in person. It has peculiar force for the entire chemical industry, however, because the production of fertilizers is a heavy chemical industry; and high grade technology, good business methods, and close chemical control are common factors in the success of all such processes.

Readers' Views and Comments

Setting a Recording Pyrometer for Cold Junction Temperature

To the Editor of Chemical & Metallurgical Engineering

SIR:—Relative to Kirtland Marsh's article in the June 29 issue of CHEM. & MET. entitled "Setting a Recording Pyrometer for Cold Junction Temperature," I wish to correct the impression that the method of "setting" a pyrometer as set forth is applicable to all pyrometers of the millivoltmeter type.

It is true that the great majority of pyrometers in use today are those calibrated for, and using, base metal thermocouples. In this type of thermocouple the e.m.f.-temperature relation is approximately linear and a unit of temperature at any point on the scale will correspond to a like unit at the instrument "zero" or calibrated cold end temperature. Undoubtedly Mr. Marsh refers to this type of pyrometer in his article.

However, there are not a few rare metal thermocouples in use at the present time, particularly in conjunction with high-speed furnaces, ceramic kilns and heat-treating work where a somewhat high degree of accuracy is desired. The emf.-temperature relation of the platinum-platinum rhodium couple of either the Heræus or Johnson, Matthey type is anything but linear. As a matter of fact, to obtain anything like consistent results, two separate formulas must be computed when calibrating this couple over its range, 32 to 3,000 deg. F.

The formula for the correction of cold junction temperatures varying from the calibrated cold junction temperature, of the Le Chatelier (Pt-Pt Rh) couple is expressed as follows:

$$E = (t_1 - t_0)x \text{ where}$$

E = actual error in deg. F.;

t_1 = cold end temperature;

t_0 = calibrated cold end temperature;

x = 0.7 for range 32 to 500 deg. F.;

0.6 for range 500 to 1,000 deg. F.;

0.5 for range 1,000 to 2,000 deg. F.

0.4 for range 2,000 to 3,000 deg. F.

It will be seen by this that any adjustment made at the instrument zero, using Mr. Marsh's method, would be a fraction of what it should be, provided the pointer is actually moved the number of degrees on the scale representing the difference between the actual cold junction temperature and the calibrated cold junction temperature.

For example, if a pyrometer is operating at 1,500 deg. F., calibrated for a cold end temperature of 32 deg. F. and having an actual cold end temperature of 75 deg. F., the error involved will be approximately 20 deg. F. at 1,500 deg. and 30 deg. F. at 32 deg. F. Naturally, as the instrument is being used at 1,500 deg. F., we are directly interested in errors that occur at that point. Therefore to adjust the instrument to read correctly we make a 30-deg. correction with the couple disconnected or a 20-deg. correction at 1,500 deg. F. The pointer actually travels the same distance in either case.

Ten degrees may not seem to be much to bother about in an industrial pyrometer installation, but there are so many other sources of error inherent in the millivoltmeter type of pyrometer that it does not seem advisable to overlook a simple adjustment of this kind.

Bridgeport, Conn.

L. W. HOPKINS.

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to the communication of L. W. Hopkins in which he criticizes the method of setting for cold junction temperature as outlined in the article entitled "Setting a Recording Pyrometer for Cold Junction Temperature" which appeared in the June 29 issue of CHEMICAL & METALLURGICAL ENGINEERING.

Mr. Hopkins' conclusions are quite erroneous and I am afraid that if he has followed out his theories in practice his temperature measurements with rare metal thermocouples have not been as accurate as he believes them to be.

Mr. Hopkins' formula for the correction of cold junction temperature gives the amount, to only a moderate degree of accuracy, which should be added to the reading of a pyrometer calibrated for a platinum — platinum + 10 per cent rhodium thermocouple when the zero setting of the instrument agrees with the calibration cold junction temperature while the actual cold junction temperature is higher or lower.

If the zero setting of the instrument is to be adjusted to correct for the cold junction temperature, the pointer should be set to the actual cold junction temperature instead of being advanced or set back an amount as determined by Mr. Hopkins' formula.

The following references discuss this subject and will substantiate this statement:

(1) The Measurement of High Temperatures, Burgess and Le Chatelier, third edition, 1912, p. 156, part 3.

(2) Supplement to Bulletin 153, September, 1919, American Institute of Mining and Metallurgical Engineers, article by Foote, Harrison and Fairchild, p. 2653, part 5.

(3) Scientific Paper 202, Bureau of Standards, p. 565, part 2.

It is evident therefore that the method of making this setting is applicable to pyrometers calibrated for rare metal couples as well as for base metal couples. I believe the only theoretical error in this method lies in the fact that since the temperature-emf. relation for rare metal couples is not linear the scale graduations on a pyrometer calibrated for these couples are not uniform. Therefore the amount of the deflection from the lowest scale division when the pointer is 20 deg. above that point will not be the same as when the pointer is 20 deg. below that point, but the difference will be so small the error involved in considering them equal, as is necessary in using the method of setting outlined in the above-mentioned article, is only a small fraction of the experimental error of making the setting.

Refining Chinese Bismuth Concentrates

To the Editor of Chemical & Metallurgical Engineering

SIR:—In "Refining Chinese Bismuth Concentrates," by Elton R. Darling (your issue of June 22) Mr. Darling explains that the hydrochloric solution containing the bismuth and antimony is treated with metallic iron and the metals precipitated; after thorough washing the precipitate is dried, and the bismuth obtained as a hydrate. This statement is open to question, as the addition of metallic iron liberates hydrogen, which in turn reduces metallic bismuth, and metallic bismuth is not converted to bismuth hydrate by simple drying, nor is it soluble in hydrochloric acid solution.

This would necessitate a different method of handling the bismuth and antimony metallics.

GEORGE DIEHLMAN.

New York City. Chief Chemist, Williams Harvey Corporation.

To the Editor of Chemical & Metallurgical Engineering

SIR:—May I say in reply to Mr. Diehlman that the process described is being used on a commercial scale with good results. As it works so well, it will not necessitate a different method of handling the bismuth and antimony metallics.

If my statement is wrong, perhaps he can account for the good results obtained in another way.

Recovery of Volatile Solvents by Bregeat Process

To the Editor of Chemical & Metallurgical Engineering

SIR:—We are glad to see that our article entitled "Recovery of Volatile Solvents by the Bregeat Process" (published in CHEMICAL & METALLURGICAL ENGINEERING, vol. 24, p. 916, May 25, 1921) has been of sufficient interest to bring forth the comments by J. C. Lawrence of Blair, Campbell & McLean, Ltd., Glasgow, Scotland—the American offshoot of which Mr. Lawrence states is the American Chemical and Sugar Machinery Company—as published on p. 93 of your July 20, 1921 issue.

With regard to this history of solvent recovery in England as described by Mr. Lawrence, it is noted that he fails to give the names and fails to state the locations of the English solvent recovery plants to which he refers. Such being the case, we cannot reply or make specific statements in regard to these plants of which Mr. Lawrence claims knowledge. The writers believe that they are familiar with all plants—of any importance at least—where solvent recovery has been attempted either in England, on the Continent or in America. We believe that each and every statement in the article, and particularly those referred to by Mr. Lawrence, are correct. The writers regret that Mr. Lawrence has not been more specific.

Concerning our summary, which Mr. Lawrence states seems to him to "require considerable modification," we believe that up to the time Bregeat started his work no company put its whole energy into the one field of solvent recovery and that the statement made, which Mr. Lawrence misquoted, and which should read as follows, is correct. "Until the Bregeat Process had been developed solvent recovery was not an industry by itself. The Bregeat Process is responsible for bringing solvent recovery out of the class of an incidental and casual art into that of an independent and well-established business."

The writers believe, in turn, that Mr. Lawrence's statement in his last paragraph to the effect that "Both

British and American firms . . . have been building and installing solvent recovery equipment of the highest type for several years" needs decided modification. That the recovery systems attempted prior to Bregeat were not of the highest type is proved by the fact that they made little or no impression on the commercial world. In many instances they were replaced or are supplemented by Bregeat plants.

The Slip Interference Theory of the Hardening of Metals

To the Editor of Chemical & Metallurgical Engineering

SIR:—The paper in your June 15 issue by Jeffries and Archer on "The Slip Interference Theory of the Hardening of Metals" will doubtless, as you suggest editorially, produce considerable discussion. My reaction on reading it the first time was one of amazement that a problem which has thus far baffled metallurgists could have such a reasonable and simple solution. Careful consideration by many minds may modify certain details, but I believe the main argument, based as it is on several generally accepted theories, will be widely accepted.

The theory, which seems to be well nigh flawless when applied to most metals and alloys, is more vulnerable when applied to steel. Perhaps carbon exists as such and cementite forms simultaneously with its separation, though I still doubt it. Perhaps the much discussed beta iron must be abandoned by its friends and supporters, though this is still an open question. Are either of the above points essential to a maintenance of the theory? They may at first thought seem to strengthen it, but it seems to me that the theory will still apply and much controversy be avoided if the points in question be made a side issue.

The internal strains set up in steel on quenching undoubtedly produce hardening in ways directly in line with the theory. These strains have often been referred to, but if a direct measurement of them has ever been made it has not come to my attention. An indirect illustration may be of some interest. A cylinder of 0.70 C steel 6 x 6 in. was quenched from 900 deg. C. in tap water. A thermocouple had been placed in a 3-in. hole at the center to study the rate of cooling. The quenching strains split the cylinder and it was found that the protection tube of the thermocouple was crushed and the diameter of the hole in the steel reduced to one-half its original size at the center of the specimen. A force to do this must be of very great magnitude, and it is not surprising if grain growth is prevented and slip produced, which will account for the hardening regardless of whether beta iron or carbon atoms are present.

Educational Motion Picture on Abrasive Industry

The completion of a new educational motion picture illustrative of the mineral industry is announced by the Bureau of Mines. The "Story of Abrasives" shows the generation of hydro-electric power at Niagara Falls, its utilization for the production of carborundum and aloxite, and finally the numerous interesting applications of abrasives.

The Use of Oil in Cleaning Coal

Coal, Pulverized by Wet Grinding, Is Agitated with About 30 per Cent of Oil, Causing the Formation of an Amalgam of Clean Coal and Oil and Separation of a Refuse Practically Free From Combustible Matter

BY G. ST. J. PERROTT* AND S. P. KINNEY†

Foreword

BY O. P. HOOD‡

DURING the war certain suggestions concerning power production were made by Walter E. Trent to the War Inventions Board, and at the request of the War Department facilities for experimental work were provided on the grounds of the Bureau of Standards.

The experiments were along the line of controlling the conditions of combustion in a closed space. In order to reduce slag troubles, experiments were carried out for removing ash from powdered coal. After the war, work along this line was continued, resulting in the Trent process, which agitates or beats together powdered coal, water and oil.

A new technology had previously been given to ore preparation by the use of small quantities of oil in water with froth flotation, and although the methods, results and mixtures of the Trent process were quite different, yet the same physical phenomenon of differential wetting was used, and the possibility of there being interesting results in fuel technology was evident. A co-operative agreement was entered into, whereby the Bureau of Mines was to investigate the underlying physical and chemical facts and make them public, and the Trent Corporation was to pay the cost of the investigation.

The several reports as made have been available to any one interested, and are now to be published. While the Bureau of Mines felt justified in investigating the physical phenomena so far as might be done in a laboratory, and so far as public interest might reach, no attempt was made to discover the commercial possibilities which development might bring. The question of commercial possibilities must be left for commercial enterprise to answer.

Briefly, the process consists in agitating together powdered coal, water and oil. This produces a partly de-ashed plastic fuel, called an amalgam, the oil selecting the coal particles and largely excluding the water and ash. The amalgam can be freed from water mechanically held by working much the same as butter is worked. The amalgam can be burned in several ways; for example, it may be shoveled, or forced through pipes by pressure; it can also be stored, under water if desired.

The laboratory results immediately suggest many interesting possible applications. For pulverizing fuel, wet grinding presents many advantages over dry grinding, provided the water can be eliminated afterwards.

To be able to reduce the ash in coal may make available great quantities of low grade coals and material now considered as waste at the mines.

If an oil is used which can be distilled at a temperature below the distilling temperature of the coal, powdered fuel is reclaimed from the amalgam and the oil may be re-used. If a heavy oil be used and distilled to dryness, a coke product may be recovered, although the coal used may have had no coking quality. If the distillation proceed only to a heavy pitch, a mass suitable for briquetting may be made.

In distilling oil mixed with a finely powdered material the distillates are similar to those obtained by distilling under pressure, so that the distillation of an amalgam of coal and oil gives quantities often more favorable than the sum of the separate distillations of the coal and the oil.

The amalgam can be used for a gas-making fuel, and gas-house tar emulsions can be dehydrated by mixing with powdered coal, the amalgam being retorted for further gas making.

Graphite ore can be separated from its gangue, and coke can be separated from flue dust by using the Trent process. Clean coal in anthracite sludge will make an amalgam if oil is added.

This brief sketch of possibilities revealed by small-scale laboratory work shows that the field for investigation and development is large. The general results show that real benefits are physically possible by treating coal in this manner. The Bureau has interested itself more particularly in the ash separation phenomena or the cleaning of coal, as outlined in the following paper, and in the distillation of the amalgam.

Laboratory Studies of the Trent Process

When a mixture of pulverized coal and water is agitated with oil in an amount equal to 30 per cent of the weight of the coal, a clean separation of a considerable part of the mineral matter is obtained. The carbonaceous material forms with the oil a pasty agglomerate which is heavier than water, while the mineral matter which was physically separated from the carbonaceous material by the fine pulverization remains suspended and can be drawn off with the water.

HISTORICAL

The history of coal washing has been similar to that of ore concentration. Hand picking has been supplanted by jigs, jigs have given way to tables in the treatment of the finer sizes of coal, and of late much attention has been given to the possibilities of froth flotation and other methods making use of the selective action of oils.

†Assistant metallurgical chemist, Bureau of Mines.

‡Chief mechanical engineer, Bureau of Mines.

Bacon and Hamor¹ in discussing the problem of the utilization of fuels, describe experiments carried on at the Mellon Institute by Dr. C. B. Carter on froth flotation of coals. He found that the combustible matter contained in washer waste of all grades could be almost completely removed by suitable oil flotation, with a recovery of combustible matter between 70 and 90 per cent. Best results were obtained with washer waste crushed to pass a 48-mesh screen. The coal particles showed maximum floating properties when they were sharp, angular, and lustrous. Grinding in machines of the disk type was found to destroy these physical properties and to make the yield of recovered coal from refuse ground in this manner small and its ash content high. Estimates showed that a plant to handle 500 tons daily of ordinary bituminous coal washer waste would cost \$135,000. With such an installation it was estimated that coal could be obtained from refuse containing 65 to 70 per cent ash to the extent of 75 per cent of the total coal present, in the form of dry 25 per cent ash concentrate at a cost of \$1.84 per ton. Pyrite was found difficult to remove by froth flotation.

Ernest Bury² and co-workers describe an investigation of froth flotation of coal carried out at the works of the Skinningrove Iron Co., England. These workers were able to obtain concentrates analyzing 9 to 14 per cent ash from washery wastes containing 40 to 75 per cent ash. The tailings contained 76 to 89 per cent ash. The authors believe that a considerable amount of pyrite may be removed by the process, although no sulphur analyses are given. The washed product, which forms as a thick heavy stable scum on the water surface of the froth boxes, contains about 50 per cent of moisture. This concentrate is discharged into revolving filters of the Oliver type, drained under suction, and discharged as a filter cake containing 10 to 15 per cent of moisture. The cost of cleaning coal by froth flotation is estimated as not greater than the cost of jig washing. In regard to the scope of froth flotation in coal cleaning, the authors state as follows: "The flotation method does not, of course, compete with washers treating nut coal for sale on the open market for boiler firing, etc.; it can be employed only where the original coal is fine or where crushing is part of the normal treatment—that is, for coking, gas-making, briquetting, coal dust firing, colloidal fuel, etc."

NATURE OF MINERAL MATTER IN COAL

The mineral matter in coal is classified (1) according to its physical state of subdivision as intrinsic and extraneous and (2) according to its chemical composition as shale, clay, slate, sand, calcite, and pyrite. Intrinsic impurities are those which are present in a very fine state of dissemination throughout the coal substance and are not separated from the coal substance even by very fine pulverization. This intrinsic mineral matter is partly derived from the original material and partly deposited during the laying down of the coal bed from external sources by sedimentation and precipitation. Extraneous impurities occur in the form of partings, veins, and nodules or may be impurities mechanically mixed with the coal during the process of mining. Part of this extraneous mineral matter is

removed by the standard methods of washing coal, the amount removed depending on the fineness of crushing necessary to physically separate mineral matter from coal substance, and on the size of crushed coal which the washery can efficiently treat.

DIFFERENCES BETWEEN COAL AND ORE CONCENTRATION

There are certain obvious differences between concentrating coal and concentrating ore. In ore concentration the valuable material is heavier than the gangue and constitutes a small percentage of the total material treated. In coal concentration, the valuable material is lighter than the refuse and constitutes a large percentage of the total material treated. Furthermore, there is a larger difference in specific gravity between values and gangue in ore than in coal. Gangue in ore varies in specific gravity from 2.5 to 3.0 and values vary from 4 to 8, while the mineral matter in coal (with the exception of pyrite) varies in specific gravity from 2 to 2.7 and the clean coal concentrate from 1.2 to 1.7. Again, coal contains *extraneous* mineral matter easily separated by crushing and *intrinsic* mineral matter, none of which can be separated except by very fine pulverization. The crushed raw coal which is to be concentrated may contain particles of coal of varying gravities containing varying amounts of inseparable ash, making a clean separation impossible at the degree of fineness employed with ordinary washing methods.

One of the early processes of concentrating ores which made use of selective wetting was the Elmore bulk oil process. Elmore mixed the ore with several times its weight of water and an equal weight of oil in a revolving drum. After gentle agitation, the mixture was run into a spitzkasten, where the water and gangue settled to the bottom and were removed. The ore was separated from the oil by a centrifugal apparatus. Froth flotation, employing an amount of oil equal to about 1 lb. per ton of ore treated or less than the recovery losses in the bulk oil processes, has superseded the Elmore process in the treatment of ore.

Since the further history of the coal concentrate is to be different from that of the ore concentrate, it does not necessarily follow that methods using relatively large amounts of oil are impracticable for concentrating coal even though such methods have been practically abandoned in ore concentration practice. The ore concentrate is to be passed through a metallurgical operation for the recovery of the pure metal; the coal concentrate is to be used ultimately as a fuel and in many cases is to be subjected to distillation for the production of coke. The mixture of coal and oil may be burned without further treatment or it may be carbonized with the formation of coke and recovery of the oil and by-products from the coal. If the oil employed contains a considerable percentage of pitch, it may serve to make coherent coke from feebly coking coals.

SCOPE OF WORK OF THE BUREAU OF MINES

The work at the Bureau has been carried out rather on the fundamentals of the bulk oil method than on its economic aspects. Experiments on a laboratory scale have been made to determine for a variety of coals the ash and sulphur removal, combustible recovery, and oil losses with different oils, different methods of agitation, and various degrees of fineness of pulverized coal. The experimental procedure followed has aimed to obtain data giving a complete balance sheet of the process.

¹Bacon, Raymond F., and Hamor, William A. Problems in the Utilization of Fuels, *J. Soc. Chem. Ind.*, vol. 38, June 30, 1919, pp. 161-168.

²Bury, Ernest; Broadbridge, Walter, and Hutchinson, Alfred: Froth Flotation as Applied to the Washing of Industrial Coal. *Trans. Inst. Mining Eng.*, vol. 60, February, 1921, pp. 243-253.

The bulk oil method of cleaning coal depends upon the same principles of selective wetting which have made possible froth flotation of ores and have been voluminously discussed in the literature of flotation. When oil is stirred into a suspension of coal in water, the first tendency is probably the formation of a suspension of droplets of oil in the mixture. The coal particles are, however, so readily wet by oil in preference to water that the globules rapidly become small agglomerates of coal and oil. These agglomerates tend to adhere to one another, entrapping water in the spaces between them and forming the pasty mass which precedes the breaking of the mixture. As a result of further agitation, the small agglomerates coalesce into larger granules and finally coalescence reaches a point where a large amount of water is released from between the particles and the separate granules are visible. With further agitation, the granules agglomerate into larger masses and if sufficient oil has been added, finally form a more or less homogeneous mass.

The best conditions for rapid formation of this amalgam³ are (1) low surface tension between coal and oil, (2) a high surface tension between coal and water, and (3) a high surface tension between oil and water. Or in other words, the reaction will take place most readily (1) with a coal which is very readily wet by oil, (2) with a coal which is not readily wet by water, and (3) with an oil which does not readily form emulsions with water. From (1) and (2) we should expect that the bituminous coals and graphite should respond to treatment most readily and the lignites least readily. From (3) we should expect gasoline and the higher paraffine oils to form an amalgam more readily than benzene and the higher aromatics and that the presence of substances in water or oil which tend to lower the surface tension between water and oil, would make the formation of the amalgam more difficult. Particles of refuse which have been physically separated from the clean coal particles by the preliminary pulverization, will be easily removed if they are readily wet by water in preference to oil and removed with difficulty if they have any tendency to be wet by oil. Hence we should expect that shale, clay and gypsum would be readily removed suspended in the water but that pyrite might tend to remain in the amalgam.

METHODS AND APPARATUS FOR LABORATORY SCALE WORK

Coal is pulverized to pass a 65-mesh screen in a laboratory disk crusher. For finer meshes the coal is then ground in a porcelain ball mill with an equal weight of water, for periods varying from 4 hr. to as long as 60 hr. when extremely fine grinding is desired (as fine as 800-mesh has been obtained in this manner). The coal is washed from the ball mill into a settling jar, from which after settling has taken place and some of the water has been decanted, it is transferred to a small electrically stirred glass churn—300-g. samples of coal have been employed in most of our work and have been agitated in the churn with about 900 cc. of water. A sufficient quantity of oil is added—about 25 per cent of the weight of the coal for a coal containing 25 per cent removable refuse—and agitation is carried on until the agglomerate of small egg-shaped granules known as the amalgam is formed.

³In ordinary technical usage, amalgam refers to an alloy of a metal with mercury, but the term is correctly used according to Webster's dictionary, to refer to any "mixture, compound, or union of different things."

AMALGAM GRANULES, NATURAL SIZE

The amalgam and water and suspended refuse are poured onto a 100-mesh screen and washed with water. The amalgam is then placed in the churn and washed with fresh water and the process repeated until no further mineral matter is removed.

After the amalgam has been separated from the refuse and the refuse filtered on a weighed paper, the products for analysis are:

- (1) Amalgam, consisting of purified coal, oil, and 10 to 30 per cent water.
- (2) Refuse, consisting of mineral matter, a small amount of combustible matter, oil, and water.
- (3) Refuse water, consisting of all the water used in the process with the exception of that retained in the amalgam and filtered refuse, a small amount of dissolved mineral matter, and under certain conditions possibly emulsified oil.

Before analysis can be made, both amalgam and refuse must be separated from oil and water. This separation must be done in a quantitative way so that oil losses, if any, may be determined. The obvious way of separating the oil is extraction of amalgam or refuse with a solvent which dissolves the oil but does not affect amalgam or refuse. If this solvent boils at a higher temperature than water, the water may be condensed and measured, thus determining amounts of oil and water in one operation. Due to the large amount of water in amalgam and refuse and the difficulty of accurately sampling the wet amalgam, it has been found more practicable to subject the whole amalgam and refuse to a separate distillation at 110 deg. C. in which water is caught and measured. The dry material is then extracted with benzene to determine the percentage

of oil. When a volatile liquid such as benzene is used in making the amalgam, distillation determines the amounts of both water and benzene and no extraction is necessary. Even when heavy petroleum oils are used in making the amalgam, it is best to dry in the still because a small portion of the oil always comes over with the water. Drying in an open dish would thus give rise to an unaccounted for loss of oil.

ASH REDUCTION AND COMBUSTIBLE RECOVERY

In calculating the efficiency of the process, several values are of interest; three of the most important being (1) per cent ash in the oil-and-water-free cleaned coal; (2) per cent ash reduction; (3) per cent combustible recovery. The first two values are qualitative measures of the efficiency. Per cent ash reduction equals the per cent ash in the raw coal minus the per cent ash in the cleaned coal, divided by the per cent ash in the raw coal. Per cent combustible recovery is a quantitative measure of the efficiency of separation of combustible matter from mineral matter. It is

equal to
$$\frac{C - rc}{C}$$

where *C* is the per cent combustible matter in the raw coal, *c* the per cent combustible matter in the refuse, and *r* is the per cent refuse by weight of the raw coal.

In calculating the amount of combustible matter in coal or refuse, it must be borne in mind that combustion of carbon is not the sole reason for loss in weight when coal is ignited in the analytical method for determina-

tion of ash. There is always a larger amount of mineral matter in coal or refuse than represented by the percentage ash as determined by the ordinary analytical method. For example, a refuse which shows 85 per cent ash remaining after ignition to constant weight at 750 deg. C. does not contain 15 per cent combustible matter. Several factors contribute to this loss in weight: Combustion of carbonaceous material; decomposition of carbonates; oxidation of pyrite to Fe₂O₃ and SO₃, and combination of part of the SO₃ with oxides formed from decomposed carbonates; loss of water of hydration from clay and shale.

Water of hydration varies from 2 to 12 per cent of shale, calcium carbonate is present in small amounts in the coals of the Appalachian fields, but may run as high as 50 per cent of the ash of some of the Illinois coals. Parr⁴ has proposed a formula for calculating the corrected ash which involves the per cent carbon occurring as carbonate in the unburned coal. In our work, time has not been available for the determination of carbonate in the refuse and the corrected ash has been determined as follows:

Ash corrected = 1.08 ash — $\frac{21}{40}$ S

Any correction factor must of necessity be an approximation, the correctness varying according as the composition of the ash varies from the assumptions made in deriving the formula. The water of hydration which

(a) Carbonized at 500 deg. C.

(a) Carbonized at 500 deg. C.

is present in shales may vary from 2 to 12 per cent. Part of the sulphur is present as organic sulphur while the formula assumes the sulphur is all present as pyrite. Since little organic sulphur is removed with the refuse, the sulphur correction is fairly accurate.

Table I gives a description of the coals discussed in the present article. These coals are referred to in the remaining paragraphs as noted in the column under "designation."

Table II gives averages of results with a number of typical coals of the United States. The coals were pulverized to 65 mesh and ground for 6 hr. with an equal weight of water in a laboratory ball mill before treatment by the Trent process. The oil employed was in all cases a grade of Navy fuel oil running 125 seconds on the Saybolt viscosimeter at 25 deg. C. The specific gravity of the oil was 0.875 (30.0 deg. Bé.) at 20 deg. C.

The results as set down are for the most part self-explanatory. It will be seen that ash reduction with most of the coals tested is good, varying from 30 to 75 per cent. Sulphur reduction is fairly good in the case of anthracite coals but low in the case of bituminous coals. With these latter coals just sufficient sulphur is removed to keep the sulphur content of the recovered coal about the same as that of the raw coal. Combustible recovery is with a few exceptions better than 95 per cent.

SULPHUR REMOVAL

The removal of pyrite from coal by any process depending on the selective action of oils is considerably more difficult than the removal of other mineral matter such as shale or slate. Pyrite is readily wet by oil and particularly when in a fine state of sub-division tends to attach itself to the coal-oil agglomerates rather than remain suspended in the water. Separation is accomplished with greater ease from anthracites than from bituminous coals. This difference in behavior of anthracite and bituminous coals is shown in the following analyses giving the percentage of total sulphur, sulphate sulphur, pyritic sulphur, and organic sulphur in a bituminous and an anthracite coal before and after treatment by the Trent process. It will be seen that in the treatment of anthracite coal, the pyritic sulphur almost disappeared from the recovered coal, while in treating the bituminous coal there was still a considerable percentage of pyritic sulphur remaining in the recovered coal.

A study of synthetic mixtures of coal and pyrite was made with a view to determining definitely the percentage of pyrite which might be removed from a mixture in which the pyrite was known to be separated from the coal particles. With mixtures of bituminous coal and pyrite ground to pass a 200-mesh sieve, separation of about 60 per cent of the pyrite was obtained by means of the Trent process, but practically no separation was obtained when this mixture was ground to 600-mesh or finer. Better separation was obtained with mixtures of anthracite coal and pyrite. The pyrite refuse separated

from the various mixtures always retained considerable amounts of oil, pointing to the fact that where separation of pyrites was obtained in the coarser mesh mixtures, this pyrite was mechanically separated from the amalgam by reason of its high density and still retained a film of oil. Coal pyrite containing about 46 per cent sulphur was used in the experiments. It was found possible to make an amalgam of the wet ground pyrite alone with very little of the pyrite remaining suspended in the water.

Results point to the desirability of preliminary water concentration of high sulphur coals for removal of pyrite before treatment by the Trent process.

OIL EMPLOYED IN PROCESS

Any oil or organic liquid not miscible with water may be employed in the Trent process provided its viscosity is not too great. The heavy topped crudes may be employed if the water used in the process is heated, thus reducing the viscosity of the oil. Certain commercial emulsions such as water-gas tar or B.S. petroleum emulsions have been successfully employed. Here again the viscosity must not be too great. B. S. refinery settlings of the consistency of cup grease were not found to be satisfactory at ordinary temperatures. An oil of viscosity equal to 135 sec. (at 25 deg. C.) on the Saybolt viscosimeter gives satisfactory results. When oils of viscosity equal to 400 sec. and upwards are employed, it is necessary to employ heated water to secure best results. Using an oil with a viscosity equivalent to 4,000 sec. Saybolt, at room temperature, it was found necessary to heat the water to 70 deg. C. to effect formation of the amalgam.

Apparently the efficiency of ash separation begins to diminish when an oil greater in viscosity than about 40 sec. Saybolt is employed. Combustible loss in the refuse is somewhat less with the more viscous oils. Considerably more of the liquids of low viscosity such as benzene and carbon tetrachloride must be used to obtain a coherent amalgam than of the oils of higher viscosity.

In the greater part of our work, oil has been used in an amount equal to 0.3 lb. per lb. of dry cleaned coal. If a coal contains 25 per cent of removable refuse, it will be necessary to use 450 lb. or about 62 gal. of a light fuel oil per ton of raw coal treated. With coal ground to pass a 200-mesh screen, this quantity of oil produces an amalgam in granules about $\frac{1}{8}$ -in. in diameter. If finer ground coal is employed, it may be necessary to use as much as 0.4 lb. of oil per lb. of dry cleaned coal. It is best to work with as small an amount of oil as possible because better washing of the amalgam is possible when the granules are fairly small, and the resultant cleaned coal contains less ash.

OIL LOSSES

Emulsification. Although at first sight it might be thought that considerable oil would be lost as a result of emulsification in the water, experiments have shown no appreciable loss due to this cause. Apparently the presence of finely pulverized coal in the water effectively prevents emulsification. As a matter of fact, certain commercial emulsions such as water-gas tar and B. S. emulsion are broken down by the addition of pulverized coal and may be used as oils for carrying out the Trent process. Even if a certain amount of oil were retained in the water, the use of this water over again after separation of the refuse, would eliminate loss from this source.

Absorption in the refuse. The oil retained by the refuse is seldom more than 1 per cent of the total oil used and frequently is practically zero. In certain cases where a large amount of refuse high in carbon and pyrite has been removed, the oil absorbed in this refuse has been as much as 10 or 15 per cent of the total oil used.

Volatilization. Volatilization losses are negligible with the heavier petroleum oils but of course quite appreciable in the case of gasoline or benzene. It is hardly likely, however, that such volatile oils will be used in any commercial application of the process.

Our results point to the conclusion that oil losses in the first stage of the process, i.e., agitation and separation of refuse, will be negligible. Recovery of oil from the amalgam by distillation is another matter and one outside the scope of the present article.

AMOUNT OF WATER RETAINED IN THE AMALGAM

An amalgam in granules $\frac{1}{8}$ -in. or larger usually retains 8 to 12 per cent moisture which will not drain out of the mixture, in addition to the hygroscopic moisture of the coal. It has been found possible to reduce this moisture to about 5 per cent by passing through a kneading machine of the meat chopper type. In an amalgam of very fine granules, the moisture content may be as high as 30 or 40 per cent. A large part of this moisture occurs as a coating of the small particles and is separated by further agitation or the addition of more oil to effect the formation of larger granules. The size of the granules depends upon the amount of oil used, the size of the coal particles, the method of agitation and time of agitation and to some extent on the character of the coal. Certain sub-bituminous coals require more oil to produce granules of a given size than do the bituminous coals or anthracite.

Brisk agitation of the kind given by rapidly revolving paddle blades is most efficient in separating mineral matter from coal and in securing rapid formation of the amalgam.

TIME REQUIRED FOR FORMATION OF THE AMALGAM

Coals differ very much in the rapidity with which they form the so-called amalgam. As a general rule, it may be stated that coals containing more than 3 or 4 per cent hygroscopic moisture as received will be difficult to work. When they contain 20 or 30 per cent moisture as do the lignites, separation is practically impossible even with prolonged agitation.

It has not been found possible to get good separation of carbonaceous material from mineral matter by treatment of the raw lignite. Lignites are very readily wetted by water, and once the lignite is well wetted with water, either by wet grinding or by soaking, the water is not readily displaced by oil. On agitation of a wet ground mixture of lignite with oil, there is some tendency for separation into layers of coal-oil and refuse-water, but no formation of the compact agglomerate of coal and oil which takes place with bituminous coals or anthracites. Microscopic examination of the mixture shows globules of oil suspended in the mixture of lignite and water indicating a high surface tension between the oil and the coal-water mixture.

Inspection of Table I will show that the two samples of lignite were carbonized at 500 deg. C. before treatment. Mere drying of the coal at 110 deg. C. is not sufficient. The structure of the coal is not changed by such treatment and the water so driven off is re-absorbed

when the coal is soaked in water prior to treatment by the Trent process. It is necessary to carbonize the lignite at a sufficiently high temperature to so change its structure that it is no longer hygroscopic. When this is done and the carbonized material finely pulverized by grinding in the ball mill, the formation of the amalgam takes place readily although a large ash reduction is not obtained with the brown woody lignites. The mineral matter in these lignites is apparently very finely disseminated throughout the coal substances and complete separation is not attained even at the finest degree of pulverization possible by grinding in the ball mill or about 5 microns (0.005 mm.).

In considering the efficiency of the Trent process in cleaning a given coal, we must then consider a third factor—time of agitation—in addition to ash reduction and combustible recovery. This factor assumes importance with the sub-bituminous coals and lignites. Obviously, overhead expenses will become greater as the time of agitation increases and there will be a length of agitation beyond which it will not be profitable to go. In the following table are set down analyses of a number

Name of Coal	Time of Agitation		H ₂ O	Vol. Matter	Analysis Fixed Carbon	Ash	Sulphur

of coals together with the time for which it was found necessary to agitate these coals when treating them by the Trent process. Two figures for time of agitation are given, the first column being the time the mixture was agitated before a separation into small agglomerates of coal and oil were visible. At this time the granules of coal and oil are soft and cannot be separated from the refuse by screening. After a further period of agita-

COMPARISON OF WET AND DRY BALL MILL GRINDING OF ANTHRACITE CULM AND UPPER FREEPORT BITUMINOUS COAL

Original samples first ground dry to pass a 200-mesh screen. Right-hand ordinate represents calculated mesh of screen through which entire sample would pass at time of grinding indicated.

tion, the granules become larger and more coherent, and may be filtered from the refuse and water by screening. The figures in the second column show the total time taken for agitation and screening of the amalgam and for the several agitations in fresh water for removal of the last traces of refuse.

The Trent process is unique among coal cleaning methods in that it treats coal in a very finely pulverized condition. Any advantages which are obtained by treatment of finely pulverized coal are advantages peculiar to the process. In the course of the investigation, a considerable amount of work has been done to determine the relation between fineness of grinding, ash removal, and combustible recovery or in other words to show to what degree of fineness it is necessary to grind different coals in order to secure optimum separation of mineral matter from combustible matter.

It was found that grinding finer than 200-mesh does not give sufficiently greater ash reduction to pay for the increased cost of the finer pulverization. The percentage of combustible matter in the refuse decreases with finer pulverization but it may not be sufficient to warrant the added expense of grinding from 200-mesh to 600-mesh or finer. Sulphur reduction is in general at a maximum with the 200-mesh material.

A number of comparative determinations of the fusibility of ash in raw and cleaned coal were made. Where any considerable amount of ash has been removed, the ash from the cleaned coal shows either a slightly higher softening temperature or larger softening interval. This was not true in the case of the bituminous coal from Oklahoma.

SUMMARY

This paper has presented the results of laboratory-scale tests of the efficiency of the Trent process in cleaning coal. A noteworthy feature of the operation of the process is the cleanness of separation of mineral matter from combustible matter. Combustible recovery has averaged better than 95 per cent. High ash reduction has been obtained with the bituminous coals and anthracites. Sulphur reduction has been good in the case of anthracites but poor with the bituminous coals. It has not been found feasible to treat the lignites without preliminary carbonization, due to the difficulty of forming a coherent agglomerate of the raw lignite and oil. Finer pulverization than 200-mesh does not give a sufficient increase in ash reduction with most coals to warrant the added expense of the longer period of grinding. Any oil whose viscosity is not too great may be employed in the process. Oil losses in the refuse or water are apparently negligible.

Beet-Sugar Industry in Northern France

France before the World War had attained a high rank among the sugar-producing nations. From its beginning under the First Empire, attaining in 1830 a production of 3,000 tons, it reached 272,000 tons in 1884, with 148,000 hectares (365,714 acres) in cultivation. In 1901-2 France planted 312,000 hectares (770,965 acres) of beets and refined 1,051,000 tons of sugar. This was the largest annual production recorded and is attributed to favorable legislation then in force. The convention of Brussels, which suppressed the practice of subsidizing sugar exports, had thereafter an unfavorable effect upon the sugar industry, so that in 1913-14 only 216,200 hectares (534,230 acres) were planted and only 712,000 tons of sugar produced.

At the outbreak of the war the invasion of the northern department reduced by 54 per cent the acreage planted. The bad quality of the seed, the scarcity of labor, and the persistently increasing difficulty of procuring fertilizer diminished the yield by about 57 per cent, as the following table will show:

Season	Acreage Hectares	Sugar Refined Metric Tons	Season	Acreage Hectares	Sugar Refined Metric Tons
1914-15.....	98,250	302,000	1917-18.....	66,305	200,000
1915-16.....	63,209	135,000	1918-19.....	59,908	110,000
1916-17.....	60,000	185,000			

NOTE—One hectare equals 2.471 acres.

The difficulty of bringing in colonial or other sugar forced the government to restrict consumption, which fell from 710,000 in 1914 to 412,000 tons in 1919, of which last 300,000 tons were imported. At the end of 1919 the price of sugar was fixed by the government at 290 fr. per 100 kilos; a decree of June 28, 1920, raised it to 310 fr. Quotations on uncontrolled sugar rose rapidly to 400 francs during the month of August, and declined rapidly in October, and in November it was quoted at 170 fr. for 100 kilos.

Out of about 210 sugar factories that were running in France before the war 170 were located in the invaded departments: Nord, Pas-de-Calais, Somme, Aisne, Oise, Marne, and Ardennes. Of these 135 were damaged by the German invasion. These damaged factories had a total capacity of 490,000 tons of sugar each season of about 75 days per year.

The total damage is estimated at 250,000,000 fr. (value in 1914). Almost all these establishments will require total rebuilding. In 1919 a few plants in the Oise, which was only moderately damaged, and one in the Nord, recommenced work. In 1920 three damaged factories in the Nord, one in the Somme, and three in the Aisne resumed activity, with a total capacity of 3,000 tons of beets per day. The advanced state of reconstruction of factory building, and the manufacture of apparatus permit the estimate that during 1921 six plants in the Nord, one in the Pas-de-Calais, one in the Somme, and four in the Aisne will resume operations. As well as can be at present foreseen, about 20 plants will recommence work in 1922, and the whole program of reconstruction will be completed in 1925.

It is estimated that out of the 135 damaged plants, about 20 will be abandoned entirely, or for a number of years, or will be employed in other industries. Among those in process of rebuilding, a certain number will increase their former capacity, several plants being consolidated in one new one. The number of establishments will be reduced, but the total capacity will not follow the same diminution. The forecast of the future sugar production is given as follows:

1920-21.....	350,000	1923-24.....	550,000
1921-22.....	460,000	1924-25.....	580,000
1922-23.....	530,000	1925-26.....	600,000

The materials and machinery necessary to be replaced or repaired is large, and for the present, French foundries and machine shops are counted upon almost entirely. Fortunately the rapid reconstruction of the industrial plants of northern France have permitted them to take care of orders since the end of 1919. American and English constructors have been temporarily eliminated from the market on account of the exchange rate. German bids have not been much lower than the French for this work, and in view of the uncertainty of deliveries no orders have been given in that quarter. The reconstructed factories will in most cases be equipped with new and improved machinery.

The Colloid Chemistry of Petroleum

A Description of the Two-Phase Petroleum System Found in Oil Emulsions —Emulsifying Agents—Types of Emulsions—Breaking an Emulsion— Effect on Lubrication and Plant Practice—Products

By FRED W. PADGETT*

COLLOID chemistry has lately been defined¹ as the chemistry of bubbles, drops, grains, filaments and films. To anyone familiar with petroleum and its products this definition suggests an important relation to hydrocarbon technology. That petroleum and petroleum distillates are of a colloidal nature has been indicated by several investigators. Ostwald² entertains the belief that high-boiling petroleum fractions are to be regarded as iso-colloids in which the disperse phase and dispersion means possess the same or analogous chemical composition. Pyhäälä³ considers that crude petroleum is a sol, of which the disperse phases are solid gels, such as asphalt, together with liquid particles. Holde⁴ has made the following observations concerning petroleum oils and distillates: Mineral oils are to be regarded as colloids. A solution of precipitated lime soap in benzene and in benzene-alcohol also behaves as a colloid. The heavy, opaque mineral oils, which are regarded as solutions of asphalt and lighter mineral resins in mineral oil, behave as colloids when viewed in benzene solution. Reddish yellow machine⁵ oils and white paraffin oils displayed a bluish cone of light containing amicrons. Small quantities of crystallized paraffins dissolved in benzene gave no cone of light, but in larger quantities a cone of light and submicrons were to be seen which became more intense or numerous the more concentrated the solution. Submicrons were scarcely to be found in Russian petroleum free from paraffin, but were readily detected in paraffin-base petroleum from America. The fluorescence of petroleum has been attributed to the colloidal nature of the product, but Brooks and Bacon⁶ reported that the fluorescent material was not adsorbed by fullers earth, and that, when a highly fluorescent oil was diluted with kerosene, filtered and carefully dried, there was no reaction with the ultramicroscope.⁷ Brooks and Bacon's view is that fluorescence is caused by a small quantity of aromatics, such as chrysene, pyrene and fluorene.

OIL EMULSIONS

An emulsion consists of drops of one liquid suspended in another liquid. Dispersed systems of this type, particularly the oil-water emulsions, are of practical importance in the technology of petroleum production and refining. The problem before the technologist may be to resolve the emulsion which is already

formed, or, on the other hand, may be to prepare a product which will form a stable emulsion; therefore a knowledge of the theory of emulsification,⁸ especially if it is a good working theory, is of practical value.

Stable emulsions of any considerable concentration of dispersed phase must necessarily contain a third substance, an emulsifying agent, which is in colloidal solution in one of the phases, but is precipitated by the other.⁹ Sometimes the emulsifying agent is not colloidal, but gathers at the interface in finely divided form, provided the substance adsorbs both phases simultaneously.

EMULSIFYING AGENTS

What is the mechanism of a stable emulsion? Will the dispersed system be an oil-in-water emulsion, or the opposite, a water-in-oil emulsion; or both together? This may be illustrated by considering a hypothetical mixture of neutral oil and distilled water, the latter containing the emulsifying agent, potassium oleate, in colloidal solution. The addition of the soap to the water has lowered the surface tension on the water side of the interface more than on the oil side; consequently the interface will tend to curve so as to be convex on the water side, producing an oil-in-water emulsion when the mixture is shaken.¹⁰ But there is nothing to prevent the drops from coalescing unless they have acquired like electric charges, have become surrounded by an adsorbed film of emulsifying agent, or are exceedingly small. If the drops have become surrounded by an adsorbed film of emulsifying agent, then the permanency of the emulsion will depend upon the stability of the film. If the emulsifying agent goes into colloidal solution with one of the phases, but is precipitated by the other, then the latter phase is dispersed and it will be possible to disperse water in oil, or oil in water, depending upon whether or not the emulsifying agent is a "hydrophobe" or "hydrophile" colloid. Sodium and potassium soaps are soluble in both water and oil, but, according to Fischer,¹¹ the soap, when dissolved in water, exists as a hydrated colloid which is not soluble in oil.

Is it always necessary to agitate violently a mixture in order to produce an emulsion? This will depend upon the "aggressiveness" of the emulsifying agent, and oils can be prepared which display such a marked

⁴Z. angew. Chem., vol. 31, p. 2138 (1908).

⁵That optical heterogeneity of lubricating oils exists has been demonstrated by Dunstan and Thole (J. Inst. Pet. Tech., vol. 4, p. 191 (1918)), but they find that the degree of dispersion is high.

⁶J. Ind. Eng. Chem., vol. 6, p. 623 (1914).

⁷Unless oils are carefully dried and filtered they will show particles under the ultramicroscope and wrong conclusions as to the true dispersed nature of the product may be drawn.

⁸On modern conceptions of emulsions see Clayton, J. Soc. Chem. Ind., vol. 38, p. 113T (1919). Bancroft's classics on the subject appeared in J. Phys. Chem., vol. 16, pp. 177, 345, 739; vol. 17, p. 501; vol. 19, pp. 275, 513. See also Thomas, J. Ind. Eng. Chem., vol. 12, p. 177 (1920).

⁹Emulsifying agents giving colloidal solutions in water (hydrophiles) are sodium and potassium soaps of oleic acid, and gums such as gum tragacanth. Those giving colloidal solutions in oil (hydrophobes) are soaps of calcium, aluminum, magnesium, etc.; also lamp black.

¹⁰If both emulsions (water in oil and oil in water) are produced, it is reasonable to expect that one will be only temporary.

¹¹Science, vol. 43, p. 468 (1916).

tendency to emulsify that, when they are poured upon water and permitted to stand, an emulsion results.¹²

TYPES OF EMULSIONS

Crude petroleum often comes to the surface emulsified with water; upon standing, a product known as "bottom settlings" collects in the storage tanks. These emulsions may be temporary, semi-permanent or permanent, and it is therefore evident that a method which has proved successful in breaking up one type of emulsion may be wholly unsuited for another. In the case of crude oil the stabilizing or emulsifying agent may be asphaltenes, finely divided clay or dirt, or possibly soaps formed by the interaction of the salts in the water with traces of organic acids in the oil; then, too, the acquirement of electric charges of like sign by the drops of water may produce the effect of an emulsifying agent.¹³ Combinations of the above-mentioned emulsifying or stabilizing agents may be of significance in regard to the stability of oil-field emulsions.¹⁴ Generally, the more viscous an oil the more readily will it hold dispersed material, such as water and earthy matter.

As an example of the variability in character of crude oil emulsions, there may be mentioned a laboratory experience in the case of two crudes, one of 21 deg. Bé., very asphaltic and quite viscous, the other of 27 deg. Bé., less asphaltic and viscous than the first. Both oils were from the same lease, but from different sands, and both contained water in form of emulsion. Upon attempting to distill the first-mentioned oil it was found that the distillation could be carried out without the necessity of adding a solvent to bring over the water, although there was some bumping at the lower temperature where this occurred. In the case of the second oil, however, even after the addition of gasoline, or benzene and toluene, the distillation could not be completed without the oil foaming violently into the condenser when a certain point was reached. Only after diluting the crude with 15 per cent of light gasoline, permitting the mixture to settle, and drawing off the oil above the bottom settlings, was it found that a distillation could be made successfully even though some water was still present. The difference in behavior between the two oils is thought to be due to the presence, in the latter case, of finely divided clay or dirt.

BREAKING AN EMULSION

Many methods of resolving crude oil emulsions have been proposed and the most important may be enumerated as follows: Heating in various ways in open and closed systems; alternating- and direct-current electricity; centrifugal action; filtration, and chemical agents. Filtration through a filter composed of excelsior is advocated by one company which has a patented filter on the market. The writer has not had the opportunity of testing this method with emulsions of various types. The oil proceeds upward through the filter and, according to the claims, there is a considerable break in the emulsion with consequent separation

of B. S. As a chemical method there may be mentioned water-soluble soap, which has a tendency to produce the opposite kind of emulsion from that existing, the effect being to break up the emulsion already formed. Sherrick¹⁵ has been able to discharge a crude oil emulsion by the use of ferric nitrate,¹⁶ having previously made the observation that the drops of water in this particular emulsion were negatively charged. In actual practice it may be found advantageous to utilize combinations of the methods mentioned above. Thus, one company has developed a process which is a combination of closed heating, settling, direct-current electricity and centrifugal action. The writer is of the opinion that most crude oil emulsions may be successfully and economically resolved¹⁷ by means of a closed heating system, properly designed to prevent the loss of volatile constituents; and that the more refractory emulsions will be treated ultimately by a method which is one of mild heating and contact with a substance which is slightly, if at all, consumed. There are also prospects of new electrical processes.¹⁸

The field is not the only place where troublesome emulsions are encountered in the petroleum industry. During the refining of lubricating oils with sulphuric acid, refractory dispersed systems of oil and water are likely to develop in the later stages of the process. In the laboratory it has been found that the formation of emulsions under these circumstances may be minimized if the alkali solution used is concentrated and the agitation is carried out with a hot solution.

EMULSIONS AND LUBRICATION

For general lubrication some engineers prefer an oil which will emulsify with water; but for use in continuous circulating systems, oils which possess sufficiently high resistance to emulsification are essential, since permanent emulsions would cause difficulties in the filtering and settling chambers where the process of purification usually consists only of screening, heating, settling and filtration. The recovery of used lubricating oils, such as those from crankcases, involves the removal of dirt which has accumulated from extraneous sources, colloidal decomposition products due to the more severe heat-treatment of the oil, water in form of rather permanent emulsion, and high ends from the gasoline used as fuel. Therefore the recovery of this type of used oil presents rather more difficulties than in the case of ordinary lubricants used in continuous circulating systems.¹⁹ The production, during refining, of lubricating oils possessing high resistance to emulsification depends to some extent upon the character of the original crude oil, but more particularly upon the proper method of refining.

In plant and laboratory practice, wherever oil and water come into contact, emulsions are likely to be formed which may result in problems of major impor-

¹²In this connection consult the work of Roon and Oesper, *J. Ind. Eng. Chem.*, vol. 9, p. 156 (1917).

¹³See Sherrick, *J. Ind. Eng. Chem.*, vol. 12, p. 133 (1920).

¹⁴Richardson's definition of Trinidad asphalt from a colloidal standpoint will illustrate this: A suspension of relatively large-sized mineral particles in an extremely viscous medium, together with highly dispersed mineral matter in colloidal form intimately mixed with an emulsion of thermal water with the bitumen present. The colloidal mineral matter present has a high adsorption capacity for the bitumen of the asphalt, *J. Phys. Chem.*, vol. 19, p. 245, (1915).

¹⁵Sherrick, *J. Ind. Eng. Chem.*, vol. 12, p. 133 (1920).

¹⁶Ferric chloride solution discharged the emulsion, but also produced jellies which were discharged by sodium nitrate.

¹⁷It may also be practical to study conditions in the well and to devise ways of preventing or minimizing the formation of emulsions as the oil comes from the sand to the storage tank. See McCoy, Shidel and Trager, *Bull., A. I. M. E.*, August, 1919, p. 1513.

¹⁸Other methods proposed for breaking up emulsions in general involve the use of sodium salts of sulphonates; heating under pressure; freezing; filtration through amorphous calcium and magnesium carbonates; various electrolytes, such as acids, aluminum chloride, cupric chloride, barium chloride, etc. The concentration of the electrolyte is of importance.

¹⁹One method is to blow the oil with steam, then to agitate with sodium carbonate solution, or a mixture of sodium carbonate and sodium soap. Final percolation of the dried oil through fuller's earth ought to be advantageous.

tance, but often are but passing incidents of the day. An interesting phenomenon may be mentioned in connection with the operation of absorption gasoline plants. An investigation of slight discrepancies in determining the gravity of the charged absorbing oil disclosed the fact that the rapidity with which the sample was collected from the high-pressure oil-line effected the apparent gravity of the sample, due to the formation of an emulsion between the oil and a small quantity of water generally present. The rapidly drawn sample possessed the lowest apparent Baumé gravity, and this was also lower than that of the oil on its way from the vent tank to the still, for the reason that a large proportion of the water in the vented oil had been relinquished at the vent tank.

Another incident, reported by J. D. Underwood, may be noted in passing. An undesirable emulsified product was being produced from the water-trap attached to the expansion box of a steam-still, and was collecting in the separatory basins. Experiments with the product developed the fact that a small quantity of silt was present, probably acting as an emulsifying agent. The temperature in the expansion box was controlled by a direct spray of water in the auxiliary tower and the silt in the emulsified product no doubt originated from this source. Cleaner water used as a spray probably would have obviated the difficulty.

EMULSION PRODUCTS

In the preparation of certain petroleum products it is necessary to compound mixtures which will produce with water emulsions of a high degree of permanency. Examples are emulsifiable cutting oil (sometimes containing emulsifying agents in the form of phenolates, sulphonated castor oil or soaps), used for the lubrication of the cutting edges of tools; and spraying mixtures for trees, which have been prepared by the use of emulsifying agents in the form of water-soluble soaps, also finely divided basic copper and iron sulphates.¹⁹ Detergent soaps²⁰ with a petroleum base may be compounded by dispersing mineral oil in a mixture of water and soap, stabilized by means of a suitable fourth substance. The resulting product, which is of a semi-solid consistency, when properly used, produces a lather which carries away the main portion of the oil. Products of this character combine the detergent action of ordinary soap with the solvent action of the oil. Cup grease, which is one type of lubricating grease, is manufactured by dispersing a calcium or other soap in mineral oil, and adding a small quantity of water which becomes emulsified in the oil. The addition of the water increases the consistency of the product and assists in preventing the separation of the soap in time.

EFFECT OF DISTILLATION ON AMORPHOUS WAX

The crystallization of paraffin in petroleum distillates is a subject which has always been of practical importance in petroleum refining. In the manufacture of lubricating oils from distillates containing paraffin wax, it is often customary to redistill the fraction rapidly, utilizing little or no steam, in order to produce a distillate which, when cooled, will precipitate paraffin crystals of sufficient size to permit rapid and efficient pressing, and yielding a "slack wax" which will "sweat" to the best advantage. In the parlance of the industry

this is known as "cracking the wax distillate." One explanation of why "cracking" gives a better wax is that the paraffin hydrocarbons exist as "amorphous wax" and are changed in molecular structure by cracking to "crystalline" wax. The other explanation is that upon "cracking" the viscous liquid components of the oil are altered sufficiently to permit the formation of larger crystals when the distillate is cooled. Experiments by one investigator may be cited in this connection.²¹ Natural petrolatum was partly distilled in steam and the distillate and residue examined microscopically. The crystals in the distillate were much more pronounced than in the residue; and when the distillate was melted with the residue it was found that the mixture possessed the same physical properties, and that the appearance of the mass under the microscope was identical with the original product before distillation.²² The conclusion is drawn that the crystal size is influenced materially by the viscous, non-crystalline components of the oil, and that distilling off part of the oil is equivalent to removal of heavy lubricating oil. If this always is entirely true in regard to the crystallization of paraffin in mineral oil residues and distillates, then the subject is mainly colloidal. Bergel²³ and also Fuchs²⁴ have carried out investigations which seem to be fair checks of the work of Gurwitsch, although there is still work to be done on this subject. What, for example, will be the comparative crystal sizes of paraffins of different molecular weight in the same heavy oil?

Petrolatum, which is a refined residual from paraffinaceous petroleum, may be defined from the colloidal point of view as being composed of paraffins in dispersed form in a viscous hydrocarbon medium, the latter inhibiting the deposition of paraffin. Artificial petrolatum, manufactured by adding paraffin to heavy oil, often develops a tendency to deposit the paraffin upon standing. Colloidal fuel consists of powdered coal more or less permanently suspended in fuel oil by means of suitable stabilizing agents or "fixateurs," such as soaps or creosote. These products may be prepared of such a consistency that they may be pumped through pipes and burners and may be stored under water. The "germ theory" of lubrication was suggested by Wells and Southcombe²⁵ to account for the fact that increased efficiency in the lubrication of heavy-duty bearings was attained by adding a small proportion of fatty acid to the oil. One action of the fatty acid was to lower the interfacial tension between the oil and metal, resulting in what might be termed increased oiliness. Since some of the fatty acids are colloidal in mineral oil, the idea suggests itself that other colloidal substances added to the oil may have the same effect. In fact, the relation of colloid chemistry to lubrication offers a field of study in which a solution of many of the abstruse problems may result.²⁶

An important application of colloid chemistry to the refining of petroleum distillates is in the use of fullers earth, bauxite, Japanese acid clay and other minerals,

¹⁹See Gurwitsch's "Wissenschaftliche Grundlagen der Erdölbearbeitung," p. 140.

²⁰The addition of a lighter oil, such as kerosene or naphtha, has somewhat the same effect as cracking. Cooling the distillate slowly also promotes the formation of larger crystals.

²¹Petroleum, vol. 14, p. 173 (1918).

²²Petroleum, vol. 14, p. 1281 (1919).

²³J. Soc. Chem. Ind., vol. 39, pp. 51, 60T (1920). The small percentage of fatty acid was more efficient than a much larger proportion of fatty oil.

²⁴In this connection see Dunstan and Thole, J. Inst. Pet. Tech., vol. 4, p. 191 (1918), and Alexander, J. Ind. Eng. Chem., vol. 12, p. 435 (1920).

¹⁹See Pickering, J. Chem. Soc., vol. 91, p. 2001 (1907). An important and interesting paper.

²⁰Reference is had here to that type of oil soap which contains a large proportion (40 per cent or more) of oil.

bone black, and synthetic products of a siliceous nature, as refining agents by percolation. The principal action is adsorption combined with polymerization²⁷. This method of refining offers one of the most promising fields of research at the present time in the direction of search for new and efficient substances, both mineral and synthetic, and their preliminary treatment for the best efficiency in refining. Florida earth has been used more extensively in the past than other fullers earths, but recently new products have been discovered. Death Valley clay, after a special treatment with sulphuric acid, has been found very efficient as a bleaching agent for mineral oils. Some enthusiasts predict that this type of refining agent will eventually replace the use of sulphuric acid.²⁸

The examples given above by no means exhaust the possible list of applications of colloid chemistry to petroleum. Other phenomena—in connection with sulphuric acid treatment, plumbite treatment and several phases of large-scale distillation—might be discussed at some length, but the examples already given are sufficient to indicate the importance of the comparatively new science of colloid chemistry to petroleum and its products.

Edible Oils and Bean Cake in Japan

The Department of Agriculture and Commerce lists 21,304 vegetable oil mills in Japan, employing 28,663 persons. These figures include the vast number of small hand-power mills using primitive crushing methods and scattered through the country districts. Accurate statistics from these mills are practically impossible to obtain. There are about 40 oil mills in Japan of commercial importance. Of these 20 are located in the Kobe consular district. Data concerning the total capacity of the oil mills of Japan are difficult to obtain, owing to their large number and diversity of methods and material, and the further fact that for the smaller mills there are no reliable statistics. The 34 largest mills have a capacity of about 3,570,200 gal. of oil per month. The production of oil for 1918 (the latest figures the Government departments have on the industry), which was a banner year in the industry and the mills were practically working at full capacity, was 547,671 koku (1 koku = 47.6 gal.). The hand mills are operated mainly as side lines during a part of the year by farmers or persons having other occupations. These hand mills consume by far the greater part of the oil-making materials grown in Japan.

The following seeds and nuts are utilized: Rapeseed, perilla, sesame, cotton seed, camellia seed, sasanqua seed, tea seed, wood nuts, kaya nuts, mustard and sumac seeds.

There has been no great increase in the capacity of the plants since that time. The production in 1918 was

Oil	Koku	Oil	Koku
Rape seed.....	150,455	Peanut.....	12,883
Sesame seed.....	18,358	Coconut.....	181,121
Perilla.....	21,514		
Cottonseed.....	16,152	Total.....	547,671
Bean.....	147,188		

It may be noted that the mills as a general thing do not confine their operations to any particular kind of oil, but vary their materials with the demand and the supply of raw materials.

²⁷Thiele (*Petroleum Age*, vol. 7, No. 9, p. 45 (1920) proposes the use of fullers earth as a cracking agent for petroleum oils.

²⁸Recent patents propose that gasoline, especially pyrolytic gasoline, be refined by passing the vapors over fullers earth or other substances of like nature.

Care and Use of the Hygrometer*

The correct use of the hygrometer is of vital importance in the interpretation and consequent regulation of drier conditions. Altered regulation because of a false conception of the conditions present often results in damage to materials in the chambers or kilns. Several basic practices may be suggested for the proper handling of hygrometers.

CONDITIONS UNDER WHICH A HYGROMETER SHOULD BE CALIBRATED

Hygrometers should never be assumed as registering the correct reading until their accuracy has been established.

It is not at all unusual for a thermometer to register a few degrees higher or lower than the true temperature. Each thermometer of a hygrometer should be checked against a standard thermometer of known accuracy over the range of temperature anticipated in its use. Corrections for the several temperatures may thus be determined if inaccuracy exists. Checking should be done with the bulbs of the standard and the tested thermometers close together and in the same medium and temperature of medium. The correction factor for a thermometer at a certain reading being known, it is simple enough to determine the true temperature.

FILLING AND CARE

Hygrometer reservoirs should be filled with pure water only. The open-top type of reservoir is easily filled but the inverted-tube type often presents difficulties. The latter type may be filled if submerged horizontally in a pail of water with the water level slightly above the well opening. Other methods of filling such a tube are by means of a wash bottle or small bent-stem funnel. In any case the body should be dropped below the mouth level.

It is important that the silk or muslin covering of the wet bulb be kept in good condition at all times. At least a small amount of solid material is always left in the meshes after evaporation, and sooner or later such a deposit impedes the transference of moisture. It is because of this that pure or distilled water should always be used in the reservoir and that the wick should frequently be changed.

PLACING THE HYGROMETER

The hygrometer should be placed at the exact points where information as to conditions is desired. Do not place it near a door or a wall, or where it will be subjected to direct radiation from the heating coils, as conditions at these points are probably not representative. To obtain representative conditions take an average of several readings in different parts of the chamber.

TAKING THE READINGS

In reading the wet-bulb thermometer care should be taken that there is sufficient air circulation to give the maximum evaporation rate from the bulb covering. At low temperatures, *i.e.*, up to 120 deg. F., there should be an air velocity of at least fifteen feet per second. At the higher temperatures this rate is not quite so essential. A thorough fanning of the air about the wet bulb is usually required. The lowest wet bulb reading for any air condition is the one desired.

Electric Reduction of Iron Ores

A Discussion of the Comparative Costs for the Commercial Production of Electric Pig Iron in the Shaft and Pit Types of Electric Furnaces and of the Respective Adaptabilities of These Furnaces to Local Conditions

BY H. A. DE FRIES

ELECTRIC pig iron today is produced commercially in two different ways and in two distinct types of furnaces—i.e., in so-called electric pit furnaces and in electric shaft furnaces of the Electro-Metals type. The latter being the best known, it will be discussed first.

REDUCTION OF IRON ORES IN ELECTRIC SHAFT FURNACES

The shaft type of electric furnace resembles in construction the ordinary blast furnace. It is generally designed for three-phase operation with six electrodes, or two-phase Scott connection with eight electrodes. The size mostly in use is three-phase, 3,000 to 4,000 kva., capable of producing from 25 to 30 tons of pig iron per twenty-four hours. The furnace itself and its accessories were fully described by Herlenius in *CHEMICAL & METALLURGICAL ENGINEERING*.¹

This furnace demands for a charge lump ore, and only a limited amount of fine concentrate may be added in crude form, the maximum being 30 per cent. To use a larger percentage of concentrate it is necessary first to agglomerate it.

The reducing agent most commonly employed is charcoal, which is aided by a constant volume of furnace gas circulated through the furnace. It is therefore obvious that the charge be porous. Coke has been used with varying results.

If we assume that the charge contains 60 per cent Fe, approximately 2,600 kw.-hr. is required for producing one ton of pig. About 500 lb. of lime is added for fluxing and as a reducing agent about 1,000 lb. of charcoal is required. The electrode consumption averages 16 lb.

A complete plant capable of producing 7,500 tons of pig per year will cost about \$150,000. Comparative conversion figures for the production of one ton of pig in this type of furnace are given later.

REDUCTION OF IRON ORES IN ELECTRIC PIT FURNACES

As far as the writer is aware, only single-phase and two-phase furnaces of the pit type have produced pig iron commercially. The furnaces have all been constructed on about similar lines and generally consist of a rectangular iron box with open top. This box is lined inside and the hearth is formed by a rammed-in mixture of graphite and tar, which in some instances extends clear to the top. In others the upper part of the furnace is lined with brick. One central electrode of suitable square section serves for the top electrode, whereas the bottom electrode is a graphite block imbedded in the hearth.

These furnaces are generally equipped with one single-phase transformer of from 600 to 1,000 kva. For

larger capacities the two-phase system is used. The low-tension voltage is 50-65-80 volts with full capacity at the lower voltage.

The charge can be either lump ore or all concentrate, or a mixture of the two. Lime is added for fluxing, and charcoal, coke or charcoal mixed with anthracite can be used as reducing agent. The charge is prepared on a platform level with the top of the furnace and is shoveled in continuously. Iron and slag is tapped about every three hours through a common tap hole at the bottom of the hearth. The electrode feed is mechanically regulated by push-button control and as consumed is lowered until its holder is about level with the charge, when a new electrode is inserted. The loss on electrode stumps therefore is low. The furnace itself is cooled on the outside by a waterspray.

The cost of a plant with one 600-kva. unit is about \$25,000, and for each additional unit \$12,000.

A plant at Porjus, Sweden, is equipped with two single-phase furnaces of this type with 600 kva. each, also one two-phase furnace of 1,800 kva. Here lump ore or concentrate, together with scrap, is used and the average composition of the charge for producing one ton of pig has been as follows:

3,150 lb. of 68 per cent iron ore
555 lb. of scrap
145 lb. of lime
245 lb. of silica
950 lb. of charcoal
300 lb. of coke breeze

The 600-kva. furnace produces from this charge an average of six tons of pig iron per twenty-four hours. This pig will average 3½ to 4 per cent C and 2 per cent Si. The kw.-hr. consumption averages 2,800 and the electrode consumption averages 30 lb.

Another interesting example of the application of electric reduction in pit furnaces are the runs made by Guédras & Duina.² In this instance pig iron was produced from pyrite cinders. They analyzed about 3 per cent SiO₂, 94.3 per cent Fe₂O₃, 2.8 to 3.5 per cent S and contained about 20 to 22 per cent moisture. The cinders are therefore passed through a rotary drier, which at the same time eliminates most of the sulphur and nodulizes the fine particles. The temperature in this roaster is kept at about 1,000 deg. C. The resulting product contains about 0.1 to 0.2 per cent S. This material is charged into a single-phase furnace of 1,000 kva. with 50-volt, 20,000-amp. low tension.

The furnace is constructed as an open-top furnace, with one carbon upper electrode and a graphitized bottom electrode. Lime is added to the charge and the desulphurizing takes place according to the following formula:

¹"Swedish Electric Pig-Iron Furnace," *CHEM. & MET. ENG.*, vol. 24, No. 3, Jan. 19, 1921, pp. 108-112. See also Baron Gerard de Geer, "Electric Smelting of Pig Iron at Domnarfvet, Sweden," *CHEM. & MET. ENG.*, vol. 24, No. 10, March 9, 1921, pp. 429-433.

²*La Technique Moderne*, July, 1920. See also *CHEM. & MET. ENG.*, Oct. 20, 1920, p. 795.

The carbon necessary for reduction was 450 lb. and can be added in form of coke, charcoal or as a mixture of charcoal and anthracite.

The heat balance sheet as given by Guédras & Duina is interesting:

	Cal.
Reduction of 930 kg. Fe = 930×1887	1,754,910
Reduction of 10 kg. Si = $10 \times 7,830$	78,300
Reduction of 5 kg. Mn = 5×1730	8,650
Evaporation of 165 kg. H ₂ O = 165×1549	255,585
Sensible heat in 1,000 kg. iron = 1000×300	300,000
Sensible heat in 400 kg. slag = 400×500	200,000
Losses through radiation, gases, conductors.....	259,744
Total.....	2,857,189
Against	
Heat of 212 kg. C = 212×8133	1,724,916
Heat supplied by electricity.....	1,132,273
Total.....	2,857,189

By analyzing this balance sheet it is seen that the heat of evaporation (1,549 calories) is figured for about 2,000 deg. C.³ The heat of carbon is calculated, it being entirely burned to CO₂.

We may roughly reconstruct this heat balance sheet, using Richards' figures, and then would have the following:

Heat distribution:	Cal.
Reduction Fe, 930×1746	1,623,780
Reduction Si, 10×7000	70,000
Reduction Mn, 5×1653	8,265
Evaporation H ₂ O, 165×606.5	99,073
Sensible heat in iron, 1000×400	400,000
Sensible heat in slag, 400×600	240,000
Losses.....	259,744
Total.....	2,700,862
Heat available:	
Assume charge will give up about 410 kg.	Cal.
Oxidation of C to CO = 212×2430	515,516
Oxidation of CO to CO ₂ = 223×2430	541,890
Heat of slag formation and Fe ₃ C, etc.....	60,000
Heat supplied by electricity.....	1,583,456
Total.....	2,700,862

The first balance sheet shows a requirement of $1,132,273 \div 846$, or 1,340 kw.-hr. per 1,000 kg. of pig iron; the second $1,583,456 \div 846$, or 1,870 kw.-hr. With single-phase furnaces $\cos \phi$ is generally 0.7. The actual requirement would, therefore, be 1,900 and 2,670 kw.-hr. respectively. In actual practice an average of 2,200 kw.-hr. per ton was consumed.⁴ The resulting pig iron contained from 0.01 to 0.3 per cent S. Electrode consumption was about 30 lb.

In operating electric pit furnaces slag should be based on SiO₂.2CaO, and if it is necessary to reduce its melting point some Al₂O₃ is added, the degree then being based on SiO₂.Al₂O₃.2CaO.

COMPARISON OF PRODUCTION COST PER TON OF PIG IRON IN SHAFT AND PIT FURNACES

In order to compare the two methods of producing pig iron electrically we will base our estimate on the results obtained abroad, but will modify these to suit American conditions. A comparative conversion table for shaft furnaces as well as pit furnaces will then appear about as shown in Table I.

It will thus be seen that the price of power is the principal item entering into the manufacture of electric pig iron. At today's prices for charcoal iron, about \$25 per hp.-yr. would be the limit for the eastern and central parts of the country. Conditions in the western part, and especially in the Pacific States, however, are much more favorable. From the table it will be seen that the cost of production varies only slightly whether

TABLE I. COMPARISON OF PRODUCTION COST PER TON OF PIG

Assumed: Cost of power, \$25 per hp.-yr. Lump ore or sintered concentrates, \$5 per ton. Crude concentrates, \$4 per ton. Carbon electrodes, \$8 per 100 lb. Lime, \$1.50 per ton. Charcoal, \$12 per ton. Labor, 75c. per hour. 60 per cent Fe in charge. Amortization and interest spread over ten years.

Electric Shaft Furnace, 3,000 kva.		Pit Furnace, Single Phase, 600 kva.	
Power, 2,600 kw.-hr.	\$9 10	2,800 kw.-hr.	\$9.80
Ore, 3,300 lb. @ \$5.	7.40	3,300 lb. @ \$4.	5.90
Charcoal, 1,000 lb.	6.00	1,200 lb.	7.20
Electrodes, 15 lb.	1 20	30 lb.	2.40
Lime, 500 lb.	37	200 lb.	.15
Labor, operation.	2 65	Operation.	6.00
Repair gang.	40		
Furnace repair.	10		.80
Miscellaneous power for auxiliaries, etc.	2 20		
Amortization and interest..	3.00		1.75
Total, per ton of pig.	*\$32 42		\$34.00
Yearly production per furnace	7,500 tons		2,000 tons
Plant investment.....	\$150,000.00		\$25,000.00
Plant investment per year ton of pig..	\$20.00		\$12.50

*3,000-kva. furnaces supply enough gas to fire one 10 to 15-ton open hearth; value of this gas is, therefore, about \$1 per ton of pig produced, so that the above net cost is \$31 42.

the iron is produced in a shaft furnace or a pit furnace. The difference in plant investment, however, is considerable, even if it takes three single-phase furnaces to equal the output of one shaft furnace. The cost of the shaft-furnace plant was given at \$150,000, whereas a plant with three pit furnaces would cost only \$50,000, or one-third. The labor cost may seem high for a one-unit pit furnace plant, but with three of these furnaces installed under the same roof it will approach the labor cost given for the shaft furnace. From a central station point of view, the shaft furnace will be more acceptable than the single-phase furnace and most power companies may object to a large single-phase load. This objectionable feature could be somewhat remedied by installing two or three furnaces on the same line.

However, the main advantage the pit furnace has over the shaft type is its adaptability to all kinds of ores, whether lump or concentrates, or both mixed.

This feature may be of utmost importance for working magnetite and other concentrates direct without previous sintering, and a possibility may exist even of reducing in them the concentrates from the black sands which are found so abundantly on the shores of the Pacific States. These sands as a rule carry considerable TiO₂. How far this can be removed by concentration or what influence it has during reduction the writer is unable to state. I believe, however, that 2 per cent TiO₂ in the concentrates would have little influence in the operation. It would be worth while to experiment with them in a small unit of, say, 150 kva. If such experiments should prove successful, they not only would make available a considerable new supply of iron, but there may also exist the possibility of retaining some of the Ti in the pig, which may make it more valuable for certain purposes.

ADAPTABILITY OF SHAFT AND PIT TYPES OF ELECTRIC FURNACES

In the production of electric pig iron, we have to consider two alternates:

First, if lumpy ore and sintered concentrates are available, a large unit plant is desired, the demands of the central station are strict and capital expenditure is of secondary nature, the electric shaft furnace should be employed.

On the other hand, if only crude concentrates are available, or the plant depends on a varying ore supply, no objections being raised against single-phase loads, and capital expenditure has to be limited, then the pit furnaces apparently possess considerable advantages over the shaft type.

³Heat content of H₂O vapor at 2,000 deg. C.

⁴As Richards has stated: "In properly designed furnaces the gases passing out may contain nearly equal volumes of CO and CO₂, instead of as shown. Any greater utilization of the heat-producing power of the carbon will naturally decrease the electrical energy required." This evidently is the fact with the pit furnace.

Hardwood-Distillation Industry—II

Influence of Temperature and Speed of Distillation on the Amount and Nature of the Distillates. With a Brief Review of the Crude Products Obtained by the Destructive Distillation of Wood*

BY L. F. HAWLEY†

ONE of the first questions to be asked in connection with wood-distillation is naturally in regard to the temperature at which wood begins to distill. This, unfortunately, is a subject on which much misinformation is still in circulation, owing largely to the fact that certain figures published nearly seventy years ago have been copied and recopied from one book to another until the original article has been lost track of and the methods used in obtaining the figures have been forgotten. Most articles on wood-distillation include tables showing the loss in weight of wood when heated to different temperatures. These tables are usually ascribed to Violette, but the original article is never cited and the method by which Violette obtained his figures is never described. Violette's table shows that there is a gradual increase in the loss in weight of wood with increase in temperature to which it is subjected. The point at which the drying of the wood ceases and the destructive distillation begins being arbitrarily taken as 150 deg. C., there is no break in the curve except a very slight one at about 260 deg. C. Although information has been available for some time to show that these figures are wrong, yet each new book or article on wood-distillation includes Violette's original table as showing the effect of temperature on wood.

RELATION BETWEEN TEMPERATURE AND DECOMPOSITION OF WOOD SUBSTANCE

Probably the first correct figures published on the relation between temperature and decomposition of wood substance were by Chorley and Ramsay.¹ These results indicated that there was very slight decomposition of wood below a temperature of about 270 deg. C., but that at this point the decomposition was very rapid and in fact the reaction became exothermic. These figures remained unnoticed for some time; but in 1907 Klason² and his co-workers repeated the experiments more accurately and in more detail, showing definitely the exothermic reaction and computing the amount of heat given off by this reaction.

In the case of an exothermic reaction such as this, it would not be possible to obtain a gradual decomposition with increase in temperature, as shown by Violette, since the decomposition would become very rapid at about 270 deg. C. In an endeavor to explain this discrepancy the original article³ was consulted and a satisfactory explanation obtained. The figures re-

ported by him were obtained with wood in very small cylindrical blocks about $\frac{1}{2}$ x $1\frac{1}{2}$ in. heated by a rapid current of superheated steam in direct contact with the wood, and the temperatures measured at the outlet from the retort. Experiments in distilling wood in a vacuum have shown that no exothermic heat is noticed under these conditions, and as the rapid passage of a current of superheated steam has exactly the same effect as a vacuum distillation, in so far as the rapid removal of the products from the retort is concerned, no exothermic reaction should be expected under conditions such as were present during Violette's distillations. It is hoped that Violette's figures will not be quoted again as representing the effect of temperature on wood as ordinarily heated, but that the correct and recent figures of Klason may be used instead.

There is, of course, a certain amount of decomposition of wood below 270 deg. C., but this is very slow

RETORT HOUSE, COOLERS AND CHARCOAL SHEDS
AT PLANT OF THE CLIFFS CHEMICAL CO.,
GOODMAN, WIS.

and the products given off are mostly carbon dioxide and water. At about 270 the exothermic reaction begins and the decomposition of wood into its ordinary distillation products is completed without further addition of heat. If the residual charcoal is heated to still higher temperatures it comes nearer and nearer to being pure carbon; but the volatile products given off are mostly tar and gas, and only traces of methanol and acetic acid are obtained.

Klason, who made the first measurements of the heat of the exothermic reaction, has also offered the first partial explanation of the heat given off at this

*For Part I see CHEM. & MET. ENG., vol. 25, No. 4, July 27, 1921, pp. 137 to 140.

period.⁷ By distilling wood under very low pressure and at a carefully regulated temperature, it was found possible to complete the distillation without obtaining an exothermic reaction. The products of this slow decomposition were, however, different from the original products, in that over 40 per cent of the weight consisted of a transparent red oil and much less gas and charcoal than usual were formed. This red oil when heated to about 275 deg. C. decomposed exothermically, forming considerable quantities of gas, water, a black tar similar to ordinary hardwood tar, and coke. This indicates that the first decomposition of wood by heat is not exothermic, but that some of the primary products of the distillation decompose exothermically. In any kind of practical process, however, this distinction between primary and secondary reactions is not applicable, and it may be correctly considered that wood-distillation is an exothermic reaction.

TEMPERATURE CONTROL

Temperature control, as a means of increasing the yields of methanol and acid, has always been a subject of great interest in the wood-distillation industry. Many

STANDARD CHARCOAL COOLERS

years ago Senfft⁸ published some figures which showed the effect of charging the wood into a red-hot retort as compared with starting from a cold retort. In nearly all cases the distillation in the red-hot retort resulted in a higher yield of gas and a lower yield of charcoal, tar and acid. Unfortunately the methanol determinations were not made in this study. It has been a general opinion among the distillation-plant operators that considerably higher yields could be obtained by a long, slow distillation of thirty-six hours than by the ordinary twenty-four-hour period.

Palmer's work on temperature control⁹ showed that it was possible to increase the yields of both acid and methanol by a careful regulation of the firing of the retorts, which was accomplished by watching the temperature of the vapors coming from the retort and the composition of the distillate as noticed at the mouth of the condenser. By heating rapidly at the beginning of the distillation and then checking the fire at just the right time, so as not to have the temperature carried too high by the exothermic reaction, he found it possible to complete the distillation in the usual period and still obtain an increase in yields. This seemed to check the prevailing opinion that slow distillations gave high yields and fast distillation low yields.

This opinion is undoubtedly correct under the conditions of large-scale distillations and considerable

super-heating of the walls of the retort. It has been shown, however, by Klason in the article previously mentioned, that this opinion is not correct in connection with small-scale distillations. Klason distilled wood in small glass apparatus under conditions varying from a 3-hour distillation under the highest possible vacuum to a 14-day distillation at ordinary pressures. From the results of this series of distillations it was possible to decide with considerable accuracy which products were primary products of the first decomposition of the wood by heat and which were secondary products obtained by decomposition or interaction of the primary products. It was found that methanol and acetic acid were both primary products and that their yields did not vary appreciably when varying the conditions of distillation. The speed of distillation, therefore, has no effect on the yields of methanol and acetic acid.

DISTINCTION BETWEEN EXPERIMENTAL AND COMMERCIAL DISTILLATION PRACTICE

At first glance it may seem difficult to harmonize Klason's results with the opinion commonly held in commercial operations, that high speed of distillation gives low yields of methanol and acid. We believe, however, that these apparently opposite views can be reconciled. The experimental work of Klason was carried out in very small-scale apparatus, only about 9 g. of wood being used in some of the experiments. In a case like this, rapid distillation, such as a complete distillation in three to four hours, can be obtained without any very great superheating of the walls of the containing vessels—that is, the walls of the vessel may have been only 5 to 10 deg. higher than the reaction temperature, a difference which is not sufficient to produce secondary reactions. In commercial practice, on the other hand, the cross-section of the distillation vessel is very large, and in order to finish a distillation even in twenty-four hours it is necessary that the walls of the retort during much of the distillation be heated 100 or 200 deg. higher than the reaction temperature. This means that, in commercial apparatus, high speed of distillation is obtained only by greatly increased temperature of the walls of the retort and the super-heating of the walls of the retort is sufficient to produce secondary reactions.

INFLUENCE OF THE SPEED OF DISTILLATION

Klason found that slow distillation produced more secondary reactions, since the vapors remained in the retort for a greater length of time than they do in rapid distillation. In this case the slight increase in temperature of the containing vessel in order to obtain rapid distillation does not have so much effect on the secondary reactions as the length of time which the vapors remain in the retort. He also showed that within certain limits and certain conditions of distillation it is impossible to vary the yields of methanol and acid appreciably by variation of the speed of the reaction or the pressure at which it is carried on. This does not mean, however, that there is not still a chance to obtain increased yields in commercial practice by temperature control, since present commercial plants obtain only about two-thirds of the acetic acid which can be obtained in medium-sized apparatus. Many carefully managed commercial plants obtain the apparent full yields of methanol, so that temperature control does not offer much in connection with this product.

⁷J. Prakt. Chem. (2), vol. 90, p. 413 (1914).

⁸Ber., vol. 18, p. 60.

⁹J. Ind. Eng. Chem., vol. 7, p. 633 (1915).

It has been frequently noticed that wood continuously subjected to medium-high temperatures, such as the temperatures of steam pipes containing steam under low pressure, will slowly darken and finally become a true charcoal. A commercial process was at one time developed for obtaining acetic acid from wood at temperatures below the exothermic reaction; but this was a very slow process requiring careful temperature control, and besides it gave different proportions of methanol and tar. It is apparently possible, therefore, to obtain the effects of high temperature on wood by long subjecting to lower temperatures; but this is of no importance in connection with commercial wood-distillation, which must be completed within a practical time limit.

CRUDE PRODUCTS OF THE DESTRUCTIVE DISTILLATION OF WOOD

From what has been said previously in regard to the complexity of the composition of wood and the character of the decomposition which takes place with heat, it might be expected that the chemical reaction of the decomposition would be very complex and that the products would be numerous. This supposition is correct as regards the various chemical constituents of the products, but the crude products as described in the terms used in the industry are not numerous and the general conception of the chemical composition of these crude products is not very complex. The crude products are: charcoal, vapors (pyroligneous acid and tar) and gas.

CHARCOAL

The charcoal which is left behind in the retort is usually thought of as carbon, and since this charcoal is a finished commercial product, its chemical composition is not considered important. It may be considered as being a very complex hydrocarbon, varying in composition between the extremes of wood on one hand and pure carbon on the other, depending on the temperature to which it has been heated. The commercial product usually still contains as high as 25 per cent of volatile matter. A new conception of ordinary charcoal is given by Klason, who considers it as consisting of a primary charcoal plus a secondary deposit of tar coke.

The charcoal as drawn from the retorts needs only to be cooled in order to render it safe for shipment or storage as a marketable product. In ordinary commercial practice it is cooled for forty-eight hours in coolers and then left for twenty-four hours in the open air.

Even with this cooling and air-seasoning, spontaneous combustion will sometimes take place in the charcoal. It is quite certain that this combustion is not caused by incomplete cooling or by sparks or brands which remain in the coal but by incomplete saturation of the charcoal with the gases of the air, so that with further absorption of these gases comes a slight increase in temperature, which in large amounts of charcoal may be sufficient to start combustion. The detailed mechanism of this spontaneous combustion has not been worked out and no clear theory has been developed.

CRUDE VAPORS (PYROLIGNEOUS ACID AND TAR)

The chemically valuable products of wood-distillation are contained in the crude vapors which after condensation separate into two layers: tar underneath and crude pyroligneous acid on top. Gravity and solubility are not sufficient for the complete separation of these two products, and some of the constituents of the tar are found in the pyroligneous acid and *vice versa*. Their

complete separation can be realized by fractional distillations.

The pyroligneous acid consists largely of water, but methanol, acetic acid and dissolved tar are also among the main constituents. The presence of acetic acid and methanol seems to make certain constituents of tar soluble in pyroligneous acid which are not soluble in pure water. The tar which is soluble in pyroligneous acid has a very different composition from the insoluble tar and consists largely of a non-volatile pitch containing only a small amount of oil. Many of the tar constituents, especially the acids and esters, are also present in the pyroligneous acid.

There are many other products occurring in the pyroligneous acid in small amounts which have not been identified and which are recognized only by their effect on the refining process. For instance, when the pyroligneous acid is distilled in order to separate it from the dissolved tar, it is obtained as a light-colored liquid which, having just been distilled, must contain only volatile products. Yet when the distilled pyroligneous acid is neutralized with lime and the solution evaporated, considerable amounts of non-volatile tarry material are left behind with the acetate of lime. This tarry impurity in the acetate of lime must come from

CHARCOAL GOING FROM FIRST TO SECOND COOLER

volatile constituents of the pyroligneous acid which have been decomposed or polymerized by the addition of lime. Small quantities of oils also remain dissolved in the pyroligneous acid until it has been neutralized and distilled. These oils have been separated out from the distillate and at some plants are known as primary oils or lime-lee oils. They are the most valuable raw material for making beechwood creosote.

The tar obtained in the distillation of hardwood was used as fuel without further treatment until a few years ago; but now it is common practice to distill it with steam in order to remove the acid and methanol contained in it. This process has been fully discussed in a recent publication.¹⁰

The separation of the chemically valuable products from pyroligneous acid and tar will be discussed in a subsequent issue.

WOOD GAS

The gas which is formed during the distillation of the wood has a low heating power and is ordinarily used for

¹⁰J. Ind. Eng. Chem., vol. 12, p. 684 (1920).

fuel at the plant. It contains large quantities of carbon dioxide, which accounts largely for its low heating power. Carbon monoxide and methane are the main combustible constituents, and it seems very likely that other gases which have been found in small quantities, such as hydrogen and ethylene, are obtained only as secondary products when the temperature of distillation is very high.

It has long been recognized that certain valuable products are lost in the wood gas which passes from the condensers, but there seems to be some general misunderstanding in regard to what these products may be, in what form they are lost, and by what process they may be recovered.

The first source of loss at this point is the mechanical carrying over of drops of liquid in the form of a fog or mist. This is not caused by incomplete cooling, since the fog will persist even when the condensers are working properly and the gas is well cooled. Apparently the loss in the form of fog cannot be avoided where considerable quantities of non-condensable gas pass through the condensers. The other source of loss in the gas is the vaporizing of the low-boiling constituents, which

24-CORD CHARCOAL BUGGY

will be carried off in the gas to some extent, however low the temperature of the condenser may be. The amount of the various liquid constituents therein will depend on their volatility and on the relation between the amounts of gas and volatile liquid. That is, as might be expected, the most volatile constituents are the ones which are lost in greatest proportions, and since they are among the most valuable constituents in wood-distillation, the loss from this source may be of serious consequence. Methanol, methyl acetate and acetone will be the main products lost in this way, since they not only have low boiling points but also form constant boiling mixtures with lower boiling points than the pure products themselves.

USE OF THE COTTRELL PRECIPITATOR FOR THE SEPARATION OF THE FOG IN WOOD GAS

The loss due to mechanically carried over drops of liquid in the form of a fog or mist can be partly stopped by the use of gas scrubbers in which the gas is subjected to the action of a liquid such as water. Washing a gas with water may still leave a part of this fog unprecipitated, and the best method for stopping such losses is by means of the Cottrell precipitator.

An unpublished report by the Research Corporation shows that a Cottrell precipitator on the gas line beyond the condenser will completely stop this fog, with the recovery of the products otherwise lost in this form. The amount of the material precipitated by the Cottrell process amounts to only about 1.7 per cent of the total distillate obtained at the condenser, and the proportion of valuable products in the recovered fog is slightly different from that in the condensate. The proportion of tar to pyroligneous acid is about the same, but there is a little less methanol in the pyroligneous acid from the precipitator than in that from the condenser.

During the period of high prices of acetate and methanol a few years ago it would have apparently been a profitable investment to install a Cottrell precipitator for the recovery of this material, but at present price it would not be a favorable investment.

USE OF SCRUBBERS FOR THE RECOVERY OF THE LOW BOILING CONSTITUENTS CARRIED OFF BY THE WOOD GAS

The loss of the vapors of low-boiling constituents carried off by the wood gas can be controlled to a certain extent by a lower temperature of the condenser water, but there is a limit to the recovery by this method. The only other method is a treatment of the gas with some liquid in which the volatile products are soluble and which will reduce their vapor pressure. Water would naturally be the scrubbing liquid to be used, since it is convenient and the volatile products are soluble in it.

The amount of the products which can be recovered by scrubbing with water depends upon the amount of water and the efficiency with which it is used. With large amounts of water, with complete contact between the water and the gas, and with the water and gas moving in opposite directions, it is possible to make a practically complete recovery of the vaporized products in the gas. There is a limit, however, below which the complete recovery would be impractical, since too large amounts of water would be required and the recovery from the water would be too expensive.

The kiln plants at one time in common use in northern Michigan and Wisconsin had a much larger proportion of gas than the retort plants, since large amounts of air were admitted to the kiln during the burning process. The residual nitrogen of the air and the products of combustion are, therefore, added to the normal amount of gas obtained from the distillation of the wood. Most of these kiln plants had some sort of gas-scrubbing apparatus, but it was usually small in size, and frequently pyroligneous acid was used for the scrubbing material instead of pure water. This was wrong in theory, since the gas was being washed by some of the liquid with which it was already in equilibrium, and it could not be expected that any more of the vapors in the gas could be removed by means of the liquid with which the gas had just been in contact. In some cases the first fraction from the central condensing system was used for the scrubber, and this naturally held somewhat less of the low-boiling constituents than the last fractions. This was a step in the right direction, but pure water would have been much better.

We do not know of any place where scrubbers are now used in retort or oven plants, but some interesting applications of this principle have recently been made at some of the old kiln plants. Special scrubbing towers with fresh water as scrubbing material have been

installed, and liberal amounts of water have been used to wash the gas. It is claimed that increased yields of methanol amounting to as much as 3 gal. per cord have been obtained by the use of these tower scrubbers. This is not all pure gain, since the liquor from the scrubbers contains only a small percentage of methanol, and large amounts of liquor must be handled in order to secure this increased yield. By means of a special still it is possible to recover that liquor in partly concen-

GAS-SCRUBBING TOWERS BUILT OF WOOD STAVE-PIPE, FILLED WITH BRUSH PACKING

trated form without actually distilling a very large portion of the scrubber liquors, and at small cost.

In view of these increased yields obtained with a gas scrubber at a kiln plant, it seems as if similar results might be obtained by applying this principle to the modern oven plants. Although there is a higher proportion of gas from the kiln plant, yet the concentration of the more volatile products is greater in the liquor from the oven plant, and the proportion of the total product lost in the gas might be as great in the latter as in the former. The application of this principle is, however, much simpler in the kiln plant, since here a central condenser system is used and all the gases are naturally collected at one place.

It has been reported that gas scrubbers have been used at oven plants, but that explosions occurred in them, and they were finally given up. There is, of course, danger of explosion with gas scrubbers when air is allowed to mix with the gas in proper proportions to form an explosive mixture, but ordinary care in the design and operation of the apparatus should obviate this danger.

Part III will be published in a subsequent issue.

Antimony in 1920

Except for the antimony in hard lead, no antimony has been produced in the United States from domestic ores since 1918, according to Frank C. Schrader, United States Geological Survey. This situation, however, is not considered altogether unfortunate, as our meager supply of ore may thus be kept for a time when we will need it, perhaps as urgently as we did during the World War.

Hard lead carrying about 14 per cent of antimony is a byproduct of the smelting of the precious metals, and the quantity of hard lead produced in 1920, which was 12,535 short tons, carried 2,033 tons of antimony and was obtained from both domestic and foreign ores. A small quantity of metallic antimony was produced by one smelter from both foreign and domestic ores, and about 5,000 tons of secondary antimony was recovered from old alloys, scrap, and dross.

The average price of antimony in 1920 was 8.49c. a pound. The highest price, which was reached in February and March, was 11½c., but owing to large imports and heavy offerings of war scrap and shrapnel by several governments, the price fell in December to 5½c., the lowest in more than six years.

The imports for consumption, calculated in terms of metallic antimony, were 11,768 short tons, as compared with 7,867 tons in 1919. Their value was \$1,435,823. They consisted of 1,709 tons of 40 per cent ore, 1,375 tons of 75 per cent matte, 9,817 tons of metallic antimony, and 298 tons of 80 per cent antimony oxides and other compounds.

The general imports were 12,474 tons of antimony and 1,709 tons of ore containing 682 tons of antimony. They showed an increase of about 76 per cent as compared with those of 1919. The metal came mostly from China and Japan and the ore from China, France and Bolivia. The imports of metal from China increased 175 per cent over those of 1919.

The imports of type metal were 14,944 short tons, or more than twice those of 1919. Their antimony content was assumed to be 2,063 tons, or about 14 per cent.

The exports of foreign antimony from the United States in 1920, mainly to Canada, amounted to 448 tons, more than double those of 1919.

About 1,877 short tons of antimony was in bond in December, 1920, as compared with 1,200 tons for December, 1919.

The world's production of antimony in 1920 was about 14,000 metric tons, as compared with 11,900 tons in 1919. Nearly all of it was produced in China, Mexico, and France. For several years China has produced more than 60 per cent of the world's supply.

The world's average annual peace-time consumption of antimony, not including that in antimonial lead, is about 22,000 metric tons, of which the United States consumes 7,000 tons. The United States also uses annually about 2,100 tons of virgin antimony contained in domestic antimonial lead and 3,500 tons of secondary antimony recovered from old alloys, scrap, and dross, a total of 12,600 tons.

Metallic antimony is used chiefly in alloys, such as type metal, Babbitt or bearing metal, Britannia or white metal, and antimonial or hard lead. Antimony oxides are used for making white enamel, and both oxides and sulphides are used as coloring agents and pigments.

Heat Balance of a Blast-Furnace Stove

Careful Tests by Improved Methods of a Two-Pass Side Combustion Stove at the Lackawanna Steel Co.
—Net Efficiency Found to Be 62 Per Cent—Volume of Blast Computed From Carbon
Balance, and Volume of Gas From Its Analysis, Fresh and Diluted

By D. W. WILSON*

IN THE first full year, 1920, of its operation, the School of Chemical Engineering Practice of the Massachusetts Institute of Technology has located one of its industrial stations in Buffalo at the plants of the Larkin Co. and the Lackawanna Steel Co. The experimental work forming the basis for this article was performed at the latter plant by the students enrolled in this course during 1920. Three separate tests, the last of which is given in detail here, were carried out by as many groups of students on the same blast-furnace stove, but under slightly varying conditions. The interest and enthusiasm of all the students in this work was very inspiring, and it is desired to acknowledge here the able assistance rendered by A. J. Hartsook, L. Weinberg and H. R. Couch, leaders respectively of the first, second and third groups of students performing this test.

PURPOSE OF THE TESTS

Necessarily, in this work the purpose was twofold: (1) From the students' point of view to illustrate the practical use of thermocouples and other temperature-measuring devices, as well as methods for measuring gas volumes under somewhat unusual conditions, and, further, to show the method of calculating the data obtained in this way to indicate the heat efficiency of a large gas-fired furnace: (2) from the technical standpoint—that is, the value of the results of the experimental work in and of themselves—the endeavor was made to carry out a complete and careful heat balance on a modern, well-designed blast-furnace stove, and inasmuch as tests had not previously been carried out on this installation, figures showing the utilization of heat are of considerable interest, since by comparison with other stoves of the same type it is possible to determine the relative efficiency of design, construction and operation.

TYPE OF STOVE AND ACCESSORIES

The stove itself consists of a vertical cylindrical steel shell lined with firebrick, 22 ft. in diameter by 110 ft. in height. Inside the firebrick lining it is divided into two vertical parts, one elliptical in cross-section and extending the entire height of the stove, through which space the gas is burned for heating, and the other, also running the entire height and occupying the remainder of the space, filled with firebrick laid so as to give a large number of parallel flues through which the gas must pass. This is the so-called two-pass side-combustion stove. It is equipped with two chimney valves, only one of which was in use. Gas passes through a suitable burner into the elliptical space, burns up

through it, and the burned gas passes down through the parallel flues and out to the stack, while in heating the air blast the flow of air is counter-current. The operation is necessarily an intermittent one in which the time ratio of heating and cooling a given stove is three to one, since four stoves are in use.

The gas used in this installation was cooled and cleaned before burning by a system of dry dust catchers followed by scrubbing with water. Natural draft only was used in the combustion of the gas and in taking care of the burned gases. The stove was in excellent condition, it having been in constant operation on clean gas about three years.

DESIGN OF TESTS

The tests, consisting as they did of balancing heat input against heat output, involved primarily a knowledge of the quantity of gas supplied per unit time to the stove; the analysis, calorific value and temperature of this gas; amount, temperature and moisture content of the air used for combustion; temperature and analysis of stack gas; and quantity, moisture content and temperature of air in the blast heated by passage through the stove. Details of this and other needed information may be obtained from the tables.

A suitable method of measuring the volume of blast-furnace gas passing to the stove was necessary, and was not at once apparent, since the amount of moisture and dirt in the gas was sufficient to make the use of the Pitot tube very difficult. The scheme finally adopted consisted in diluting the gas some distance back from the point of its entrance to the stove with a measured volume of air and analyzing the gas before adding the air and again after the gas and air were thoroughly mixed. Air for this purpose was measured by an orifice and delivered into the gas main by a small pressure blower. To obtain results of the needed accuracy required careful gas analyses, which, with care, however, was entirely within the range of practical possibilities. Table I contains the experimental data obtained in this way.

Another problem consisted in the estimation of the volume of air delivered to the blast furnace. This is extremely important, since the heat efficiency of the stove is based upon an exact knowledge of it. A method often depended upon and which was used in this work as a check only consists in estimating the volume from the size of cylinder, length of stroke, speed and slip-page of the blowing engines.

In this test the air volume delivered by the stove was determined by analyzing all carbon-bearing materials entering and leaving the blast furnace. This information, coupled with a knowledge of the quantities of these various materials entering or leaving the

*Director, Buffalo Station, School of Chemical Engineering Practice, Massachusetts Institute of Technology.

furnace over a given period of time, is sufficient to render possible the calculation of the air volume per unit time.

In Table I are included all the experimental measurements taken, upon which were calculated the data shown in Table II and III.

TABLE I. EXPERIMENTAL DATA

Date of test, Dec. 2-3, 1920.	
Size of stove, 22 x 110 ft.	
Size of combustion chamber (cross-section) 4 ft. 11 in. x 11 ft. 9 in.	
Length of time in service, 3 years.	
Checker opening, 5 $\frac{1}{8}$ in.	
Duration of cycle (returning to initial temperature).	
Starting temperature, 770 deg. C.	
Cycle 1—From 3:34 p.m. Dec. 2 to 1:14 a.m. Dec. 3. On gas 3:40 p.m. to 10:40 p.m. (Blast off 3.5 min.) On air 10:45 p.m. to 1:07 a.m. (Blast off 7 $\frac{1}{2}$ min.) Time extended 7 min. beyond 1:07 a.m. to allow time for stove to reach temp. of 770 deg. C.	
Cycle 2—From 1:14 a.m. Dec. 3 to 10:29 a.m. Dec. 3. On gas 1:12 a.m. to 7:55 a.m. (Blast off 23.5 min.) On air 8:00 a.m. to 10:25 a.m. (Blast off 17.5 min.) Time extended 4 min. beyond 10:25 to allow time for stove to cool to 770 deg. C.	
Net time on gas (No. 1 cycle), 416.5 min.	
Net time on air (No. 1 cycle), 141.75 min.	
Net time on gas (No. 2 cycle), 379.5 min.	
Net time on air (No. 2 cycle), 131.5 min.	
Pressures: (In inches of water unless otherwise stated):	
Blast-furnace gas in main (No. 1 cycle).....	8
Blast-furnace gas in main (No. 2 cycle).....	8
Air for dilution (in line to orifice).....	27
Orifice differential.....	12
Air blast, lb. per sq.in., avg. (No. 1 cycle).....	17.8
(No. 2 cycle).....	21.4
Barometer, lb. per sq.in.	14.8
Size of orifice for air.....	3.1 in.
Temperatures, Deg. F.:	
Blast-furnace gas in main, avg. (No. 1 cycle).....	58
(No. 2 cycle).....	54.6
Air through orifice (avg. for two cycles).....	37.0
Cold air blast (No. 1 cycle), avg.	150
(No. 2 cycle), avg.	162
Hot air blast (No. 1 cycle), avg.	1,645
Leaving stove (No. 2 cycle), avg.	1,543
Flue gas to stack (No. 1 cycle), avg.	426
(No. 2 cycle), avg.	406
Hot air blast (bustle pipe), avg.	1,196
Atmospheric Conditions, Deg. F.:	
Wet bulb.....	34.6
Dry bulb.....	37.2
Wet bulb at blowing engines, during pumping (avg.)...	36.0
Dry bulb at blowing engines, during pumping (avg.)...	39.5
Gas Analyses:	
Blast-furnace gas, 12-in. orifice differential before adding air (avg.):	
CO ₂	Per Cent 14.5
O ₂	0.1
H ₂	3.5
CO.....	24.1
CO + H ₂	27.6
After adding air (avg.):	
H ₂	2.6
CO.....	22.8
CO + H ₂	25.4
Flue gas (avg.):	
CO ₂	19.3
O ₂	1.9
N ₂	78.8
Carbon Balance:	
Carbon input, 9:17 a.m. to 9 p.m. Dec. 2 (703 mln.):	
Coke:	
Total weight charged, lb. 581,000.	
Per cent carbon, 83.8.	
Scrap:	
Total weight charged, lb. 56,000.	
Per cent carbon, 4.0.	
Limestone:	
Total weight charged, lb. 264,000.	
Per cent carbon (95 per cent CaCO ₃) 11.4.	
Carbon Output:	
Flue Dust:	
Weight per day (estimated), lb. 70,000.	
Per cent carbon, 7.14.	
Pig Iron (duration of test):	
Weight, lb. 1,047,000.	
Per cent carbon (estimated) 3.75.	
Blowing Engines:	
R.p.m., 61.2. Number of compressions per revolution, 2.	
Diameter of piston, 84 in.	
Diameter of piston rod, 16 in.	
Length of stroke, 60 in.	
Slippage (measured), 5 per cent.	
Radiation Data:	
Average skin temperature, combustion side of stove, 161 deg. F.	
Average skin temperature, flue side of stove, 108 deg. F.	
Temperature of surrounding air, 37 deg. F.	
Area of combustion side of stove, 1,990 sq.ft.	
Area of flue side of stove, 5,660 sq.ft.	
Average skin temperature of hot blast main, 90 deg. F.	
Area of exposed surface of hot blast main, 1,980 sq.ft.	

This test extended over two complete cycles—that is, two periods during which gas was burned in the stove

to heat it up, and subsequently air passed through it to be heated before its entrance to the blast furnace. An arbitrary point of 770 deg. C. was chosen as the starting point, and therefore the length of cycle is corrected to allow for the return of the stove to the initial temperature. A constant differential pressure of 12 in. was maintained at the orifice measuring the air used to dilute the blast-furnace gas. This was kept constant by proper regulation of a valve controlling the volume of air. The orifice used was sharp-edged and had a diameter of 3.1 in.

The hot-blast temperature measurements were taken by means of thermocouples both as it left the stove and at the bustle pipe. In calculating the efficiency, the bustle pipe temperature was used, allowing for radiation along the hot-blast main, and in determining the starting and ending points of the test, the temperature of the blast leaving the stove was relied upon. The cold-blast temperatures were sufficiently low so that they were obtained by the use of a thermometer.

In analyzing the blast-furnace gas the usual methods were employed for carbon dioxide and oxygen. However, hydrogen and carbon monoxide were determined very carefully by a slow combustion method, since the volume of blast-furnace gas passing to the stove was calculated on the basis of the change in the sum of these two caused by the air dilution.

In getting data for the carbon balance care was taken to extend it over a sufficient length of time to equalize any slight irregularities in operation. The possible error involved did not warrant the analysis of the scrap and limestone for carbon, and consequently figures for this given in Table I are estimates. The necessary gas analyses for the calculation of the carbon balance were obtained from the values given in Table I for the blast-furnace gas before diluting with air.

Moisture and dust determinations were made on the gas two or three times during the test.

Measurements made to determine the loss of heat due to cooling the hot-blast valve stem are not included in Table I, inasmuch as they consist merely in the measurement of the volume of water passing to and from the valve per unit time together with the change in temperature of this water.

In the determination of the so-called "skin"—i.e., surface—temperatures of the stove, use was made of an ordinary mercury thermometer immersed in mercury and insulated from the surrounding air by a small block of wood. This was so arranged as to be constantly movable over the surface of the stove.

In Table II the various computed results of importance are given.

DISCUSSION OF COMPUTED RESULTS

The air volume passing through the orifice per minute was obtained by the usual methods of calculation using 0.605 as a coefficient of discharge. The dilution of the gas by air was calculated from the change in sum of carbon monoxide and hydrogen, due to the addition of the air. The heating value of the gas was not determined calorimetrically, but was figured from the analysis of the gas.

From a knowledge of the carbon content of the stack gas and blast-furnace gas the volume of stack gas per volume of blast furnace gas was obtained.

In estimating all heat quantities involving changes in temperature of gases, the usual method was employed necessitating a knowledge of initial and final tempera-

TABLE II. COMPUTED RESULTS

Average air volume per min. through orifice at 37 deg. F. and 8 in. H ₂ O, 433 cu.ft.
Per cent dilution of gas by air, 8.7.
Average gas volume per min. to stove at 32 deg. F. and 1 atm., 5,030 cu.ft.
Calorific value per cu.ft. of dry gas at 32 deg. F. and 1 atm., 94.3 B.t.u.
Total net time on gas, 809.5 min.
(Allowance made for small amount of gas from other furnaces.)
Volumes of stack gas per volume of blast-furnace gas (dry basis), 2.0.
Stack loss per min. above 62 deg. F. (average, dry basis), 73,200 B.t.u.
Pounds H ₂ O per min. in blast-furnace gas (gas saturated), 4.0.
Pounds H ₂ O per min. in air supplied for combustion, 1.25.
Heat loss per min. above 62 deg. F. due to moisture in air and gas, 860 B.t.u.
Heat required per min. to raise air for combustion from 37 to 62 deg. F., 3,110 B.t.u.
Per cent excess air used, 28.
Pounds H ₂ O vapor formed per min. from combustion of hydrogen, 8.8.
Heat loss per min. above 62 deg. F. due to above H ₂ O, 10,700 B.t.u.
Volume of air blast per min. from blowing engine displacement (dry basis 32 deg. F. and 1 atm.), 42,200 cu.ft.
Volume of air blast per min. from carbon balance (dry basis 32 deg. F. and 1 atm.), 41,500 cu.ft.
Time on air, 273.3 min.
Heat absorbed by blast per min. (dry basis), 863,000 B.t.u.
Pounds H ₂ O in blast per min., 12.
Heat absorbed by H ₂ O in blast per min., 5,970 B.t.u.
Radiation per min. along hot blast main from stove to bustle pipe, 5,250 B.t.u.
Heat required for cooling hot blast valve and valve stem per min. (stove on gas), 5,230 B.t.u.
Heat required for cooling hot blast, valve and valve stem per min. (stove on air), 19,400 B.t.u.
Convection coefficient for loss of heat from stove surface, 2.0. (B.t.u. per hr. per sq.ft. surface per deg. F. temperature difference).
Radiation coefficient for loss of heat from stove surface:
Combustion side, 1.3.
Flue side, 1.1.
Total radiation loss from stove surface per min., 34,400 B.t.u.

tures, analyses of gas and specific heats of the various gases over the temperature ranges involved.

An interesting comparison is shown between the volume of air delivered to the furnace as obtained from displacement figures on blowing engines and by the carbon balance method. It will be seen from the values given in Table II that the agreement was very close, the two figures checking within about 2.0 per cent. In estimating the slippage on the blowing engines, use was made of the results of a careful overall efficiency test of these engines.

The values used for heat loss by radiation were obtained by estimating the total coefficient of heat transfer from stove surface to air in terms of B.t.u. per hour per sq.ft. of surface exposed per deg. F. temperature difference. This total coefficient is the sum of two independent ones, that of radiation and that of convection. The latter was estimated, allowing as well as possible for wind velocity and other modifying influences. The radiation coefficient for black bodies was figured from a knowledge of the temperature difference between the exposed surface and surrounding air, and the total radiation loss then was calculated from a knowledge of the surface exposed, temperature difference between the surface and surrounding air, the time of the test, and total coefficient of heat transfer.

SUMMARY AND CONCLUSION

The efficiency figure of 62 per cent obtained in this test indicates a well-designed and well-operated stove, as this value compares very favorably with figures given in previously published reports¹ of tests made at other plants on stoves of the same type. It is realized that the comparatively short length of this test may tend to give a higher efficiency than would be shown by

¹A. E. Maccoun, "Blast-Furnace Advancement," 1915 Yearbook American Iron and Steel Institute. A. N. Diehl, "Burning Blast-Furnace Gas," 1915 Yearbook American Iron and Steel Institute.

TABLE III. SUMMARY OF HEAT QUANTITIES

Efficiency and Heat Distribution:	B.t.u.	Per Cent
Heat Input:		
Heating value in gas	384,000,000	100.0
Heat Output:		
Heating value in flue gas	59,900,000	15.6
Heating air for combustion	2,600,000	0.7
Uncondensed water from hydrogen combustion ..	8,700,000	2.3
Heat removed by air blast	238,000,000	62.0
Cooling water for valve	10,100,000	2.6
Radiation loss	39,000,000	10.1
Unaccounted for	25,700,000	6.7

tests run over a considerably longer time. In this work no attempt was made to determine the distribution of air or gas through the checkers, since it was not practicable to do this at this time. It is felt, however, that the stack loss of approximately 16 per cent indicates fairly uniform distribution through the checkers. Considerable information might be obtained from a comparison of figures obtained here with those resulting from previous tests² on other types of stoves such as center combustion and the three-pass or four-pass, but it is not within the scope of this report to attempt such a comparison.

While the figures for radiation loss included here are necessarily more liable to error than the others of Table III, since all factors influencing it cannot be definitely determined, yet even so it is felt that it is reliable to within about 2 per cent of the total heat input. Future work should be done on blast-furnace stoves along the line of the calculation of figures giving the transmission of heat from gas to brick work and brick to air. Figures such as these, if arranged in terms of fundamental units, have the possibility of ultimately being extremely helpful in the future design of hot-blast stoves. Especially useful would be a study of the relationships between such heat-transmission figures and varying velocities of gas or air through the stove.

The author desires to express his sincere appreciation of the hearty co-operation and extremely helpful advice given by various members of the operating, metallurgical and engineering departments of the Lackawanna Steel Co., as well as by his colleagues in the School of Chemical Engineering Practice.

British Standard Leather-Measuring Regulations

On July 1, 1921, certain regulations promulgated by the British Government Board of Trade came into force, requiring every leather-measuring instrument to conform to an approved pattern verified and stamped by an inspector of weights and measures. This action has been taken in view of the increasing use of measuring instruments in the leather trade and must be complied with within a period of 12 months. Before the instrument can be passed by the inspector the templates—which are required to be provided—must be stamped at the National Physical Laboratory, and they must be subjected to a second stamping at the laboratory after the lapse of 12 months. This requirement is necessary because of the shrinkage to which templates are liable and until this has ceased the permanent area can not be ascertained.

The regulations provide for local standard templates to be kept by the local authorities, and based thereon all instruments will be verified by the inspectors at intervals of not less than six months. The full regulations have been issued under the title of "Weights and Measures (Leather Measurement) Regulations, 1921."

The Engineer's Part in Industrial Safety*

A Plea for Industrial Safety Work in Which It Is Clearly Brought Out That Properly Conducted Accident Prevention Work Pays a Larger Return on Investment and Operating Cost Than Any Other Department of an Ordinary Industrial Plant

By C. P. TOLMAN†

IN THE APPLICATION of engineering principles to safety the engineer is answering the same call of humanity to which engineers of all times have responded. There is probably no field of scientific industrial work which in any one plant calls for and can advantageously use a broader range of professional training and experience.

What is the magnitude of the problems with which we have to deal? I have before me some statistics prepared by Sidney J. Williams, secretary of the National Safety Council. We can read our answer in the following annual statement rendered and paid in full by the industries of our country in 1919:

Human lives.....	23,000	
Accidents, each causing four weeks' disability or more.....	575,000	
Accidents involving one day's disability.....	3,000,000	
Total equivalent working days lost.....	296,000,000	
At average wage of \$4 a day.....	\$1,184,000,000	
Incidental expense—medical, surgical, hospital, insurance, etc.....	\$161,000,000	
Total.....	\$1,345,000,000	
Credit—for the subsistence of 23,000 men who no longer need clothes, food, nor housing.....		\$331,000,000
Balance due.....	\$1,014,000,000	

You say perhaps it was an unusual year. Yes. In the previous year, 1918, more men were employed and the bill was 13 per cent larger.

Without further analysis we may safely agree that this waste of a billion dollars a year is great enough to demand attention. And our next question naturally is, "Can this waste be substantially reduced without prohibitive expense?" The answer is, "Yes; it has been done."

I have here totals from carefully recorded data in the files of the National Safety Council from eight widely known companies, members of the Council; in each case the accident record of one year is compared with the record of a previous year. The total number of men employed by these eight companies is 36,200. The reduction in accidents, measured by the difference in days lost per thousand hours worked, averages over 70 per cent. This is a most conservative figure, for in several cases effective accident prevention work was going on before the first of the two years compared. So we have part of our answer—it can be done.

COST OF INDUSTRIAL SAFETY WORK

Now as to the rest: Is the cost prohibitive?

On the contrary, properly conducted accident prevention work pays a larger return on investment and operating cost than any other department of the ordinary industrial plant.

This is an astounding statement, but it is borne out by fact.

A certain small company operating a coal mine with 100 men reduced its accident cost per ton 68 per cent. A large corporation tells us of a profit from its safety work of \$1,000,000 per year. These illustrations will serve as a general proof of the statement; they recite only what is to be found in the bookkeeper's balance. They tell us nothing of the incidental profits from better relations between men and management, and give no credit for the saving of human life and suffering. In the specific illustrations we shall consider only the cash profits. For with the assurance of definite profit the industrial manager need have no hesitation about undertaking organized safety work. He need fear no criticism from the owners; on the contrary, he is neglecting the owners' interest if he fails to establish the safety principle in his plant and give it that support, supervision and interest necessary for successful functioning.

Our immediate subject does not include that phase of safety work which has to do with the personal equation. Volumes have been written—available from the National Safety Council headquarters in Chicago—on the instruction of foremen and workmen, on methods of organizing shop safety committees, on medical supervision and first aid training, on the use of bulletin service, and on safe operating practices, both in general and applied to specific industries. All of this is essential to a successful safety program.

PROBLEMS CONFRONTING THE ENGINEER IN HIS INDUSTRIAL SAFETY WORK

We are here considering the relation of the engineer as such to the material rather than the human side of industrial safety.

Usually the engineer finds for his problem a plant equipped and operating. He is required to make it as safe as possible with the following stipulations:

- (a) He must not interrupt operations.
- (b) He must do nothing which would decrease output or increase cost.
- (c) He must not make changes of a character or in a manner to cause labor trouble.
- (d) He must not make changes which will affect the character of the product.

Otherwise he has a free rein.

This seems to leave little chance for accomplishment. But hundreds of engineers are doing effective safety work under just such restrictions. The work is limited, of course, to the more common measures, such as guarding machines and transmissions, general betterment of ventilation, lighting and floor conditions, etc. It is well worth while, profitable to the industry, and calls for real ability.

The design of a gear guard is not beneath professional dignity. A gear guard which answers all require-

*An address delivered before the joint meeting of the Cleveland Engineering Society and the Engineering Section of the National Safety Council, May 31, 1921.

†Chief Engineer and Chairman Manufacturing Committee, National Lead Co., and President National Safety Council.

ments satisfactorily calls for skillful design. Among other requirements we have, for example, the following:

- (a) It must be securely attached.
- (b) It must be readily opened or removed.
- (c) It should be easier to close it than to leave it open.
- (d) It must not interfere with oiling or adjustment of the machine.
- (e) It should not drip oil or grease on the floor to make a slipping hazard.
- (f) It should be designed for economical manufacture.
- (g) The means for attaching and opening should be of a kind familiar or obvious to the average workman.
- (h) In so far as possible, it should permit inspection of gears without opening or removing.

Properly designed guards may save considerable in first cost, will save much in maintenance, and will remain in use. Improperly designed guards may not afford proper protection and, if awkward to replace, are usually left off, once they have been removed.

INDUSTRIAL SAFETY PLUS WASTE SAVING

Leaving the more obvious measures incidental to safeguarding machinery, let us consider the less obvious measures for safeguarding the immediate work of the operator. At once we are in a much more profitable field of work. Most of the profit in the earlier class comes through saving in cost through the prevention of accidents, whereas in the latter class, by bettering operation from the safety standpoint, we not only reduce accident cost, but if our work is properly done we invariably increase production or save waste. As an example of the latter, in the white lead industry portable dust collectors were developed and used for sanitary reasons. Purely out of curiosity the lead dust saved was weighed. The average of all factories showed a saving of lead amounting to a return of over 30 per cent on the investment.

INDUSTRIAL SAFETY PLUS INCREASE IN PRODUCTION

As an example of increased production, in the manufacture of steel drums, using toggle drawing presses, a factory was started about ten years ago with presses operating ten strokes a minute. At this rate the loss of fingers was alarming. The presses were therefore slowed down to seven strokes per minute. The accidents were reduced, but still were serious. The superintendent then devised and installed a method of operating the clutch by a solenoid magnet. The electric circuit led through two switches connected in series. These switches were arranged to open by springs and be closed by hand. One switch was located on each side of the press frame. To operate the press the workman had to use one hand on each switch. He could not get his hand or fingers in the press while it was operating. The presses were then speeded up to twelve strokes per minute, making an increase in production of 70 per cent with safe operation.

This is not an unusual case. Semi-automatic press feeds will, while making the operation safe, increase output from 10 to 100 per cent. Full automatic feeds will better this. Ejectors or kick-outs give similar results.

Lest we get the impression that results of this sort are confined to punch presses, suppose we consider another class of machinery infamous for mutilation of hands, the circular saw.

At the National Safety Council's congress in Mil-

waukee last year during a session of the Engineering Section it developed that 70 per cent of saw accidents originate in bad condition of the saw—dull, not properly set or not properly gummed. There were men present ranging from youth to rugged age, men who had lived with woodworking machinery. And they were unanimous on this point. They were then asked if saws and other woodworking machinery were kept in proper condition as compared with the average conditions, what increase in production would result. Again they agreed—at least 20 per cent. In other words, by keeping the saws in reasonable order, the average woodworking plant would eliminate the source of 70 per cent of saw accidents and make a net gain of 20 per cent in production with the same equipment, the same labor and less power.

SAFETY WORK IN MACHINE SHOPS

Once again that we may remember we are dealing with a broad general principle and not with any one class of machinery, let us consider the machine shop. Here we have the usual groups of accidents:

- (a) The kind which may befall any workman.
- (b) Selective accidents: (1) that select the careless, indifferent, or ignorant workman; (2) that select the best of the mechanics.

Aside from the labor turnover this last is a pretty serious proposition. The statement that there is a type of accident which selects your best men requires some proof. The best known example of this type happens when your machinist uses his hand as a brake on the rim of the face plate of his lathe. The man who does this is the man who wants to see his work progress. He is not content to stand idle while his lathe comes slowly to rest. He wants to get his micrometer on the work and see the result of the cut—to get the piece out when finished, and get in the next one. So he disobeys orders—he does just what you or I would do, he is interested in his job and he takes the chance.

This hazard can be wiped out. The corrective measure involves an important fundamental principle in safety work:

Make it easiest and most effective to do it the safe way.

In this case the thing to be done is to stop the lathe. The power must first be shut off. The remedy is obvious. Equip the lathe with a brake; if it is a belt-driven lathe, use a foot pedal which when pressed first shuts off the power and then applies the brake. The almost instantaneous effect of the powerful foot brake leaves no incentive to use the hand on the face plate. If the lathe is direct-motor-driven, use a controller designed for dynamic braking.

The International Harvester Co., at its Milwaukee shops, equipped the spinning lathes with foot brakes as just described. The accident hazard was eliminated and the increased production is paying an enormous return compared to the cost of this home-made attachment.

SAFETY WORK IN DESIGNING INDUSTRIAL PLANTS

Gratifying as are the results from careful analysis and treatment of hazards where found in a going plant, there is another broader fundamental method of treatment which is occasionally open to the engineer where a new plant is being built. Shall we digress a moment to make the principle clear by an illustration? The personal experience I am going to relate is one you

have all had. Recently I visited a plant for which an expensive addition was being planned. Upon going through the plant I found an unusual equipment of machinery specially designed for the work. The machines, although performing what would be considered difficult operations, were simple in that way which bespeaks the genius of the designer. But the arrangement of the machines was haphazard. Additions had been made from time to time and the original "flow sheet" was lost to view. Had the designer of the machines viewed his whole plant as one great machine, he would have done with it as he had done with the individual machines, and the additional building, machinery and labor would not be needed. This is the general principle of engineering revision as applied to safety: Regard the whole plant as a machine. Make the whole as well as each part function for safety. The production returns incidental to safe methods for the individual machine are multiplied again when the whole plant is co-ordinated on a safety basis.

SPECIFIC CASES FOR SAFETY DEVICES

Provision for clear aisles is a safety measure. It also facilitates transfer of materials and lowers production costs. Racks and bins properly placed reduce accidents from falling objects; they also save material from injury and facilitate production.

Correct lighting equipment and correct location of machines with respect to natural light prevents eye strain; waste from faulty manufacture is also saved, and production increased.

Grouping equipment involving special hazards or bad working conditions makes it possible to treat these conditions effectively and avoid exposure of other employees than those engaged in the particular work. For example, furnaces so grouped can be hooded to carry off heat and fumes; special cool air supply can be provided. The advantages of grouping apply also when chemicals are used or dusty operations are involved.

While some of these measures can be applied to a degree regardless of general plant arrangement, all of them can be applied much more effectively if it is feasible to treat the plant as a whole.

With the growth of an industry in volume it is usual to add more and more of the small capacity units which, although suitable as to capacity in the earlier days, have been outgrown, and too many units are needed to produce the output. It is engineering revision in respect to the custom of such an industry to redesign such equipment, increasing the capacity of the unit. The reduction of hazard is twofold when this is done—first, there are fewer men exposed; second, in redesigning, the equipment can always be made inherently safer. The reduction in manufacturing cost is obviously large. In the steel industry we have a striking example of just such revision.

HUMAN EQUATION IN SAFETY WORK

It is sometimes possible to make radical changes in the general process of manufacture, avoiding hazardous features and effecting large economies in operating cost. This is all work for the engineer, some phases of it calling for broader training and experience than others. To do any of it thoroughly and well we must include that factor which we have thus far omitted, the human equation. The engineer preparing for this work must become familiar with organized safety work and the practical data which have been patiently accumulated in

the course of such work. He must respond to the spirit of the safety movement, for words and data alone will not serve him.

SUMMARY

I have tried to establish two basic principles—first, properly conducted accident prevention work pays a larger return on investment and operating cost than any department of the ordinary industrial plant and, second, make it easiest and most effective to do it the safe way.

I have shown the opportunity for the engineer in this field of work. I do not mean that he is forthwith to christen himself safety engineer. On the contrary, he is not true to the ethics of his profession or to the interest of his client if, knowing the effectiveness of the safety viewpoint, he fails to make safety a part of his professional attitude toward all his work.

The safety movement needs the hearty co-operation of the engineer.

Antiseptic Treatment of Wood Pulp Prevents Mold and Decay*

Tests show that by the addition of certain antiseptics to wood pulp it is possible to prevent to a large extent the decay and molding which now cause such serious losses in the pulp during storage. Several preservatives were found which kept groundwood pulp clean for a year under the most severe conditions which could be devised. The procedure adopted in the tests was, briefly, to inoculate the treated pulp with active mold spores and wood-destroying fungi and then to store it in warm, moist air in piles between laps of very rotten pulp.

In determining the relative suitability of the preservatives, account was taken of their effectiveness as antiseptics, poisonous properties, tendency to discolor the pulp, odor, solubility in cold water, and cheapness.

All things considered, sodium fluoride appeared to give the best results. A 5 per cent solution sprayed on the pulp at the rate of 80 lb. of dry salt to a ton of air-dry pulp, kept it practically clean for a year. A 3 per cent solution (48 lb. per ton) permitted only slight molding. This chemical is safe to handle, and produces no discoloration in the pulp.

Borax followed a close second to sodium fluoride. A 5 per cent solution (80 lb. per ton) held the pulp in good condition for 6 to 8 months. Borax is safe for workmen to handle and does not darken the pulp to an objectionable degree. Boracic acid was equal or superior to borax in effectiveness, but the greater cost throws it out of competition. Sodium dinitrophenolate in a 1 per cent concentration (2 lb. per ton) had an antiseptic efficiency equal to anything tried, but yellowed the pulp somewhat. Sodium dichromate gave less consistent results than the four chemicals mentioned, and the tendency toward browning was marked in concentrations of 2 or more per cent (32 lb. per ton). Sodium carbonate and bicarbonate, although they kept the pulp nearly free from infection for a year or more, browned and softened it too seriously for commercial use.

In the laboratory experiments, the antiseptics were sprayed with an ordinary garden sprayer on the pulp as it came from the wet machine. These experiments were followed by a mill trial in which the preservatives were applied at the press roll of the wet machine, with promising results. Improved methods of applications should make it possible to lower the concentrations and, consequently, the cost of treatment.

*From U. S. Forest Products Laboratory.

Electric Vitreous Enamel Furnace

A TWO-COMPARTMENT electric furnace for baking vitreous enamel on resistance tubes has recently been installed at the Schenectady works of the General Electric Co.

The furnace is divided by a door which can be raised or lowered when a batch of tubes is to be transferred from one compartment to the other. These tubes consist of a grooved porcelain body, wound with resistance wire; the enamel is placed over this winding. The front compartment of the furnace is used as a pre-heater where the tubes are held at a temperature of 570 deg. F. for six minutes. This is necessary, because if the body of the tube is subjected to too high an initial temperature, it will crack. The connected load on this compartment is 9 kw. and the temperature is automatically controlled by means of a thermostat. When preheating is accomplished, the work is moved into the second or baking compartment by raising the door between the two compartments. In this compartment it is subjected to a temperature of 1,650 deg. F. for six minutes, emerging from it in a finished state. The connected load in the compartment is 24 kw. and the temperature is also automatically controlled by means of a thermostat.

The heating units on both chambers are arranged so as to give a very even heat distribution and, by using thermostats, an absolutely uniform temperature is obtained during the preheating and baking periods. This furnace also possesses the further advantage in that both operations—viz., preheating and baking—can be carried on at the same time on two different batches of work.

Each compartment will hold a tray containing thirty-six tubes which weigh about 27 lb.; the tray weighs 30 lb., so that there is a total load of 57 lb. in each compartment. The dimensions of the compartments are 48 in. long, 18 in. wide and 24 in. high and the overall dimensions of the furnace are 13 x 5 x 7 ft. The heating

equipments can be made for 230 volts direct current or 220 volts single phase alternating current.

This furnace has not only saved time and floor space but has improved the quality of the finished product and has reduced the percentage of defective tubes from 20 per cent to less than 1 per cent.

Some interesting comparisons have been obtained with this furnace and an oil-fired furnace which it replaced. Working on two different classes of material—viz., push buttons and resistance tubes—it was found that the kw.-hr. per lb. of push buttons was 1.87 and the cost per lb. was \$0.023. For resistance tubes, the kw.-hr. per lb. was 0.541 and the cost per lb. \$0.006. The cost per hour of operating the oil furnace was 72c., since it consumed 6 gal. of oil costing 12c. per gal. The cost over the same period with electric heat was 41c., or a saving of 31c. per hour in favor of the electric. It is estimated that production has also been increased approximately 50 per cent.

A Convenient Formula for Diluting Solutions

BY E. J. McMILLAN*

Where large volumes of standard solutions are prepared, much inconvenience is experienced in diluting such solutions to the desired strength on account of the inconvenience of directly measuring such large volumes.

A convenient and accurate determination of the amount of diluting required to bring any solution of unknown volume to desired strength is made as follows: Titrate the original solution against the standard. Add a known but insufficient amount of the diluent and titrate against the same amount of the standard.

Let C_1 = number c.c. used in first titration.

C_2 = number c.c. used in second titration.

C_3 = number c.c. required when the solution is diluted to the desired strength.

X = the original volume before diluting.

N = the amount of diluent added.

V = volume after diluting and making second titration.

D = number c.c. required to be added to V to bring the solution to the desired strength.

$$\frac{X}{C_1} = \frac{X + N - C_1}{C_2} + \frac{C_1}{C_2}$$

$$X = \frac{NC_1 - C_1^2 + C_1C_2}{C_2 - C_1}$$

$$V = X + N - C_1 - C_2$$

$$V = \frac{NC_2}{C_2 - C_1} - C_2$$

$$D = \frac{VC_3}{C_2} - V$$

$$D = \frac{N(C_3 - C_2)}{C_2 - C_1} - (C_3 - C_2)$$

— $(C_3 - C_2)$ can be omitted without appreciable loss of accuracy.

$$D \text{ then becomes } \frac{N(C_3 - C_2)}{C_2 - C_1}$$

This calculation can conveniently be carried out on a slide rule with sufficient accuracy.

*Chemist, Cleveland Hardware Co., Cleveland, Ohio.

ELECTRIC VITREOUS ENAMELING FURNACE WITH PRE-HEATING AND HIGH-TEMPERATURE COMPARTMENTS

New Synthetic Bearing Metal

A NEW bearing material called Genelite, recently developed in the research laboratory of the General Electric Co., has given remarkable results in a series of tests made to determine its performance, both when lubricated and self-lubricating.

It consists of a mechanical mixture of a high-grade "synthetic" bronze, and graphite, the latter amounting to about 40 per cent by volume of the whole mass. Since the material cannot be melted and poured into molds like ordinary metals, its formation into bearings is accomplished by a special process. It is made from the oxides of tin, lead and copper (mixed in the proportions to form a high-grade bronze) plus graphite, all the ingredients being in a finely divided state. Graphite is added in sufficient excess quantity to reduce the oxides to the metals and still leave the required content in the finished material. The oxides are partly reduced by heating the mixture, after which it is still in powdered form, but is then pressed as nearly as possible to the required shape in massive metal molds.

In the pressed form it is still too brittle to stand handling, so it is given a final heat-treatment which reduces and sinters the metals together into a homogeneous bronze, holding the graphite uniformly distributed throughout the mass. The evenness of this distribution is shown in Fig. 1, at 100 diameters. The white spots are the bronze, and the black ones the

FIG. 1. MICROSTRUCTURE OF GENELITE. $\times 100$

graphite. The baking fixes the graphite so securely within the mass that it cannot be separated or washed out, even if the metal is lubricated. Some of the various stages of manufacture are shown in Fig. 2, in which substance number 5 is the mixture after the preliminary bake, ready for pressing, 6 a bushing

FIG. 2. VARIOUS STAGES IN THE MANUFACTURE OF GENELITE

FIG. 3. OIL SIPHONED FROM UPPER BEAKER BY CAPILLARITY THROUGH GENELITE AND WICKING

pressed from the powder, 7 a bushing after the final bake (or Genelite in the raw stock form) and 8 a finished piece. The material has the general appearance and body of bronze, but the characteristics are different. It does not machine readily by ordinary methods, but can easily be ground, which has been found to be the best method of handling it in production. Neither has it the physical characteristics of bronze, having very low tensile strength,

but being capable to withstand high compressive strains.

Another marked difference is its porosity, it being able to absorb as much as $2\frac{1}{2}$ per cent by weight of oil. This feature is made use of in some of the high-speed applications where oil is applied to the outside of the bushing and carried to the bearing surface by capillary attraction. Fig. 3 is a piece of apparatus set up to show this feature of the material. Oil from the upper beaker is siphoned to the lower one through the rod of Genelite and the woolen wick by capillary attraction.

The tests have brought out another valuable characteristic, from the user's standpoint, in that a bearing made from this material never seizes or "freezes" as these expressions are commonly understood. The metal of the shaft and bearing never flow and weld together as a result of bearing friction. If the Genelite bearing sticks, owing to having been fitted too close, examination will show that no damage has been done, either to the bearing or the shaft, and they can be reassembled after the bearing has been ground down to proper size.

One of the principal uses of Genelite is on various parts of automobile engines where lubrication is either poor or neglected altogether owing to the inaccessibility of the bearing. Places where its self-lubricating properties render it valuable are on fan bushings, clutch centering bushings, throttle control bushings, etc. Places where lubrication is apt to be poor owing to dilution of the oil by uncombusted fuel products or other cause are also helped by the installation of Genelite bearings.

Infringement of Permutit Patent

The broad patent of the Permutit Co. on zeolite water softeners was the subject of an infringement suit against the Hawley Foundry Co. and the Refinite Co., which was recently decided by Judge Hazel of the U. S. District Court at Buffalo, N. Y. The court recognized the priority of Gans' discovery of Permutit in 1906 and found that the apparatus used and manufactured by the defendant was an infringement on the Permutit Co.'s patented apparatus. An injunction was ordered against the defendants.

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Electrolytic Cell.—A horizontal diaphragm of asbestos superimposed upon a perforated iron cathode, which in turn forms the bottom of the cell, is the principal feature of an electrolytic cell patented by John M. Williams of Guthrie, Okla. In addition to its normal function, the diaphragm serves as a gasket to make a liquid-tight joint between the bottom and sides of the cell. The diaphragm is made preferably of sheet asbestos and is covered by a protecting layer of sand or finely ground glass. (1,376,495; May 3, 1921.)

Bromine Extraction and Apparatus.—When brine is treated electrolytically to liberate bromine, there are also produced considerable quantities of hydrogen and chlorine. If the succeeding steps in the extraction—viz., removing the bromine from the brine by blowing air through it, and finally absorbing the bromine from this air—are carried out in a closed circuit, there is danger of forming an explosive mixture. If the air, after removing the bromine, is allowed to escape and fresh air is drawn into the system, there may be a loss of heat. These objections are met by Herbert H. Dow in the following manner: The gas produced incidental to the electrolysis and not absorbed by the brine is withdrawn through a separate system containing a standard absorption tower to take up the bromine and chlorine. The brine is then conveyed to another system where the dissolved gases are removed by blowing out with air. This air after passing through the absorption towers necessary to relieve it of the bromine and chlorine is returned to the first blowing-out tower, thus maintaining a closed circuit throughout the system. (1,376,610; assigned to Dow Chemical Co., Midland, Mich., May 3, 1921.)

Tempering Cam Shafts.—An ingenious adaptation of electrical heating for hardening or tempering cam-shafts is described in a patent by John F. Wandersee of Highland Park, Mich. It is necessary in order to produce satisfactory cam-shafts that the cams be very hard to withstand constant wear, while the shafts must be relatively soft and tough. The hardening, which has formerly been accomplished by a long and laborious process of carbonizing and cyaniding, is brought about by placing the shafts into an ordinary electric welding machine in a manner such that only the cam itself is held between the two electrodes. Current is applied until the desired temperature is reached and the shaft is removed and quenched. (1,376,984; assigned to Ford Motor Co., of Detroit, Mich., May 3, 1921.)

Clarifying and Decolorizing Oils.—R. W. Mumford, of New York, has been granted a patent for a process of treating oils with a particular type of vegetable carbon, described as "an open-textured granular material having a porous structure representing approximately the original cellular structure of the material carbonized." This carbon is claimed to be more effective than fullers earth and the other decolorizing and clarifying agents commonly used for both vegetable and mineral oils. The patent covers different processes of applying the decolorant, one of which consists in utilizing electrically charged fields in order to facilitate the action of the decolorant. (1,377,021; assigned, by mesne assignment, to Darco Corp., of Wilmington, Del.; May 3, 1921.)

Method for Producing Zinc Chloride.—Paul Danckwardt has patented a process of preparing zinc chloride by utilizing as a source of his chlorine the residue obtained from the aluminum chloride method of oil distillation. The

residue, either as sludge or cake, is leached with water, the solution filtered and then treated with zinc ore in the proper proportion to precipitate all of the zinc. The aluminum separates out as the oxide and, if the ore used has been sufficiently pure, can be recovered as pure Al_2O_3 —a valuable byproduct. The zinc chloride solution is evaporated and then heated to a high temperature for the production of the anhydrous salt. (1,378,219; assigned to the DANCKWARDT PROCESS Co., of Denver, Col.; May 17, 1921.)

Granulating Converter Slag.—In certain smelting operations, such as the production of copper matte, converter slag is sometimes poured into the ore-smelting furnace to aid in fluxing the charge. This method is not generally satisfactory, because the stream of molten slag does not mix properly with the ore charge. If, however, as the slag is fed into the furnace, a stream of steam under relatively high pressure is projected at right angles against the stream of falling slag, the latter is disintegrated and, in a granulated form, is spread over a large portion of the surface of the charge in the furnace. (1,378,223, SAMUEL RICHARD GARR, assignor to AMERICAN SMELTING & REFINING Co., of New York; May 17, 1921.)

Recovery of Ammonia and Production of Barium Chloride.—James H. MacMahon has devised a process for recovering both the ammonia and the chlorine present in the so-called feeder liquor of the ammonia-soda process. Former practice has been to free the volatile ammonia from the ammonium chloride and to pass this liquor into the lime still, where it is decomposed to form ammonia and calcium chloride. The calcium chloride represents a waste and moreover any free ammonia present in the waste liquor is lost. If, however, the black ash of crude barium sulphide is used instead of the lime, the barium chloride obtained is itself a valuable product or can be used for producing other barium salts. The ammonium sulphide formed, if decomposed with caustic soda, will yield marketable sodium sulphide. Modifications of the methods of carrying out these processes are described by which the different products can be obtained in various degrees of purity. (1,378,593 and 1,378,594; assigned to the MATHIESON ALKALI WORKS, INC., of Saltville, Va.; May 17, 1921.)

Process of Making Calcium Bisulphite.—A calcium bisulphite solution, which is rich in free sulphurous acid, is produced in a novel manner. Instead of causing a direct reaction between the sulphur dioxide and the milk of lime or of passing the free gas through a lime tower where it meets a counter-stream of water, George A. Richter, of Berlin, N. H., first acidulates water with sulphur dioxide in an absorbing tower, and then causes the acidulated water to react with lime in a separate reacting chamber. The product of this reaction may then be further acidulated to obtain the desired sulphur-dioxide content. (1,378,616; assigned to the BROWN Co., of Berlin, N. H.; May 17, 1921.) A second patent (1,378,617) provides for the preparation of a calcium-bisulphite cooking liquor by the use of a suspension of finely pulverized limestone instead of the milk of lime described in the previous patent.

Process of Making Methanol From Methane.—Methyl chloride is produced from methane by any suitable process and then in anhydrous alcoholic solution is converted into dimethyl ether by a process of heating with caustic soda under pressure. The dimethyl ether is subsequently hydrolyzed to methanol under high pressure. The latter reaction is accelerated by the presence of free mineral acid. The conversion of the methyl chloride is carried out in an iron receptacle containing ethyl alcohol and an excess of caustic soda under a pressure of about 20 atmospheres. The final hydrolysis usually proceeds very slowly unless fairly high temperatures are used. However, by the employment of certain accelerating agents, such for example as a 20 per cent solution of sulphuric acid, the reaction can be made to produce methanol on a commercial scale using a temperature of only 80 deg. C. The final reaction is carried out in tall, narrow iron cylinders tested for a pressure of 200 atmospheres. (1,379,362; E. H. RIESENFELD, of Freiburg, Germany, assignor, by mesne assignments, to the CHEMICAL FOUNDATION of New York; May 24, 1921.)

Current Events

in the Chemical and Metallurgical Industries

Object to Volstead Act Amendment

Determined objection is meeting even the modified amendment to the Volstead prohibition act. Senator Broussard, of Louisiana, in opposing the amendment, declared on the floor of the Senate that the bill should be known as the anti-prescription bill, rather than the anti-beer bill. His contention is that the Volstead act is intended to prohibit the beverage use of alcohol, and that no administrative officer of the Government should be vested with power which enables him to interfere with the valuable formulas of legitimate proprietary compounds in which alcohol is used and which gives federal officials a control over industrial alcohol which tends to discourage its manufacture.

"The proponents of this bill," declared Senator Broussard, "forget that alcohol is the universal solvent—one of the basic chemicals. They forget that if the manufacture of alcohol is impeded, many industries suffer. One result would be that this country would have to rely largely on imports of articles for whose manufacture alcohol is necessary. They do not conceive that alcohol is as essential to many industries in this country as pig iron is to the manufacture of steel." Senator Broussard also attacked the clause in the bill having to do with the refund of taxes when alcohol is stolen or lost before entering manufacture.

Senator Stanley, of Kentucky, expressed the opinion that the committee is without realization of the far-reaching effect of the alcohol-shipment clause of the bill, and he is not inclined to believe that any Senator is so ignorant of the legitimate use of alcohol for industrial purposes as not to want to encourage its manufacture, or that any Senator should want "to mulct in ruin the manufacture of industrial alcohol, when it could serve no legitimate purpose."

Senator Brandegee, of Connecticut, called the attention of the Senate to a communication he had from a large manufacturer of flavoring extracts and fruit syrups. "As a manufacturer of flavoring extracts and fruit syrups for soda fountains," said the telegram, "it is absolutely necessary to use non-beverage alcohol in flavoring extracts and less than half of one per cent in fruit syrups to cut the natural oil in the fruit. I have no objection to national prohibition, but this amendment, if passed, will disastrously affect business."

On the other hand, H. B. Thompson, the general counsel for the proprietary association, telegraphed Senator Willis that the Senate committee amendment is satisfactory to the members of his association.

Muscle Shoals on the Tapis Again

Announcement by the Secretary of Commerce that various chemical and power companies are considering the acquisition of the Muscle Shoals project has revived interest in this matter among members of Congress. Senator Underwood contends that the only way the public can secure the maximum benefit from the water power at Muscle Shoals will be by its operation by the Government. He continues to believe that the Government likewise should operate the nitrate plant. It is very evident, however, that a majority in the Senate favors the execution of any reasonable contract with a responsible private interest.

Just at this time, there is much opposition to further appropriations. Difficulties are anticipated in securing congressional approval for the \$28,000,000 which are required for the completion of the Wilson dam, even in view of the fact that the finished project could be leased. It is apparent that the majority in Congress prefers an arrangement whereby all additional expenditures should come from private sources.

The detailed proposal of Henry Ford is now being analyzed by the Chief of Engineers.

American Ceramic Society Meeting at St. Louis in 1922

The twenty-fourth annual meeting of the American Ceramic Society will be held in St. Louis, February 27 to March 2, 1922.

St. Louis is growing to greater importance as an industrial city every year. It is one of the largest centers for refractories and heavy clay products, while enameled ware, glass, and terra cotta are abundantly represented. A week of trips for the inspection of plants would be none too long.

The Hotel Statler will be the headquarters of the society and its facilities for the comfort of the meetings are unexcelled. Large rooms for divisional meetings, with a choice of ballrooms and banquet halls for the general sessions, will be available; while the luxury of the private rooms is too well-known to need description.

It will be noticed that the date is later than is customary. The reason for this is that the month of February is buyers' month in St. Louis, and the city is overcrowded without the additional influx of a national convention. The local men therefore urged that the date be put at the very end of the month, and the decision was made in accordance with this advice.

Dye Vote Surprises Congress

The opponents as well as the friends of the limited embargo prescribed for dyes in the Fordney tariff bill were surprised greatly at the action of the House in eliminating the dye schedule from the bill. At the time the matter first went to vote in the committee of the whole, there was some doubt as to the result, but with the apparently safe margin in favor of the embargo, indicated by the vote in the committee of the whole, there was little thought that the vote would be reversed in the House proper.

As a result of this unexpected action, communications reaching the finance committee of the Senate indicate that the entire chemical industry is aroused as never before, and that a determined effort is under way to secure the reinstatement in the Senate of the limited embargo.

It is very apparent that the important relationship between the dye industry and the national defense will play an important part in the contests certain to be waged in the Senate. General Amos A. Fries, head of the Chemical Warfare Service, will be one of the witnesses called by the Senate committee. He will reiterate his declaration to the House committee that he regards the plan of the Ways and Means committee for the handling of dye imports as absolutely necessary to the upbuilding of a type of dye industry essential to the national defense. He will point out to the Senate committee the close relationship between the dye industry and the manufacture of explosives and poisonous gases.

Now that it is absolutely apparent that the permanent tariff bill will not become a law prior to August 28, when the limited dye embargo expires, an effort will be made in the very near future to put through a bill extending the temporary embargo for another six months. If that embargo were allowed to lapse, it is declared that there are enough German dyes in American bonded warehouses to supply the American demand for two years.

New Ceramic School in Canada

The University of Saskatchewan, Saskatoon, Can., is perfecting plans for the establishment of a new ceramic department, to be the first such institution in Canada. W. G. Worcester, a graduate of the Ohio State University ceramic department, has been appointed professor at the new school.

Manufacturing Chemists Make Plea for Protection

Scores of chemical products are being imported even now at prices which make American competition impossible. This is only the inception of this import movement of chemicals. Conditions abroad, particularly in Germany, have retarded that country's struggle for chemical supremacy, but from this time forward a systematic attack upon the American market is anticipated. This is one of the arguments used by Henry Howard, chairman of the executive committee of the Manufacturing Chemists' Association, at his appearance before the finance committee of the Senate. The general arguments presented by Mr. Howard were embodied in a brief which was filed with the committee, and later a number of members of the association called attention to specific commodities for which increased rates were needed.

T.A.P.P.I. Notes—Plans for Fall Meeting

Among acquisitions to the membership list of the Technical Association of the Pulp and Paper Industry not previously reported are the following whose applications have been approved by the executive committee:

A. M. E. Johnstone, technical representative, Wallace & Tiernan Co., Newark, N. J.; L. J. List, engineer and sales manager, Samuel M. Langston Co., Camden, N. J.; Harold A. Morrison, sales engineer, Oliver Continuous Filter Co., 33 West Forty-second St., New York City; William J. Orchard, engineer and sales manager, Wallace & Tiernan Co., Newark, N. J.

VOCATIONAL EDUCATION TEXTBOOKS

An appeal made by the committee on vocational education of the pulp and paper industry at the annual meeting of the association in April has met with generous response in some quarters. Following the receipt of letters from the committee stating the present situation with regard to funds for the continuance of the work, \$50 contributions have been received from each of the following: McDowell Paper Mills, Manayunk, Pa.; Hummel & Downing Co., Milwaukee, Wis.; Pittston Paper Corporation, Pittston, Pa.; Kalamazoo Vegetable Parchment Co., Kalamazoo, Mich.; Bardeen Paper Co., Otsego, Mich.; Tidewater Paper Mills Co., Brooklyn, N. Y.

At the annual meeting of the Technical Association, a contribution of \$500 was made by the Champion Fibre Co., Canton, N. C., and the New York & Pennsylvania Co. donated another \$500, which, with the contributions listed, make a total of \$1,300. The amount which it is hoped to raise in the United States to defray expenses of producing the complete set of vocational education textbooks on the manufacture of pulp and paper is \$7,500. It will be recalled that \$5,000 was subscribed by the Canadian Pulp and Paper Association as a body, the pro rata assessment on United States manufacturers being \$7,500. There is yet to be raised by contribution or otherwise the sum of \$6,200. The importance of continuing the work of the vocational education committee does not require to be emphasized in any way and it is hoped that firms who have delayed in responding to the appeal of the committee for funds will at once communicate with R. S. Kellogg, secretary of the committee, 342 Madison Ave., New York.

TECHNICAL ASSOCIATION PAPERS

Series IV of *Technical Association Papers* has been issued and mailed to members. This makes a volume of 174 pages and covers. The volume contains verbatim reports of the various group meetings held during the annual convention of T.A.P.P.I., and all of the papers and their discussions are presented in full. The account of the banquet proceedings is especially interesting and entertaining. The after-dinner speeches are given in full and it is seldom that a more admirable mingling of grave and gay has been presented. Chemical warfare and the sources of the deadly gases used are described in a speech of great rhetorical ability by Prof. Bogert of Columbia University, while Ellwood Hendrick, president of the Chemists' Club, is represented with a whimsical discourse on odors which he announced as a "Homily on Olfactics." In his inimitable

fashion Dr. Hendrick spoke of odors in literature, the mnemonic associations of smell, and the function of smell in insects and animals. The relations of paper and electricity are touched upon by Calvert Townley, assistant to the president of the Westinghouse Electric & Manufacturing Co., who, however, did not stick closely to his text and told many stories. Paper's place in our daily life and the appalling situation which would develop if newspapers were abolished were the subject of an address by Arthur L. Dawe, secretary of the Canadian Pulp and Paper Association.

Technical education in general was the theme of a speech by Philip T. Dodge, president of the International Paper Co., whose talk is reported in full. Mr. Dodge made a plea for the interchange of technical knowledge and drew a picture of a project he had in mind for the establishment of a great central college or school for teaching the art of papermaking. It is a thoughtful speech well worth pondering. Series IV of *Technical Association Papers* sells for \$3 a copy.

PLANS FOR JOINT FALL MEETING

Preliminary arrangements for the joint fall meeting of the Technical Association and the Superintendents Association are nearly completed. The heads of the local committees have been in conference with the secretary of the association at Washington and sub-committees appointed. The committee appointed by the Superintendents Association to co-operate with T.A.P.P.I. consists of the following members: Robert B. Wolf, 42 Broadway, New York City; Thomas F. Heberly, Schmidt & Ault Paper Co., York, Pa.; Nelson R. Davis, S. D. Warren Co., Cumberland Mills, Me.; James A. Ramsay, Dill & Collins Paper Co., Manayunk, Pa.; Leon K. Detwiller, Diamond State Fibre Co., Bridgeport, Pa.

Fred A. Curtis, chief of the Paper Section, U. S. Bureau of Standards, Washington, D. C., is chairman of the committee of arrangements for the fall meeting of T.A.P.P.I. and the Superintendents Association, assisted by Daniel A. Smith of the District of Columbia Paper Manufacturing Co. and Grellet N. Collins of Dill & Collins Paper Co., Philadelphia.

Asks Hearing on Metric System Bill

An early hearing on his bill providing for the compulsory adoption of the metric system, after a period of ten years, has been asked by Senator Ladd of North Dakota. Senator LaFollette, the chairman of the committee on manufactures, states that he is disposed to grant the hearing but that he is dubious of securing the consent of any three members of his committee to act as a sub-committee to conduct the hearings. Senator LaFollette states that there is so much legislation at this time which appeals to him as being of greater importance that he cannot undertake the conduct of the hearings personally. He expresses the opinion that it will be difficult to find three members of the committee willing to take the time for metric system hearings during the consideration of the tariff and other matters of first importance.

Senator Ladd's plan is to conduct a short hearing at the earliest possible time in order that the outstanding arguments may be presented by each side, thus giving the public an opportunity to study the relative merits of these contentions. After the convening of the regular session in December, it is his desire to re-open the hearings and go into the question in a comprehensive way.

Byproduct Coke Statistics

A monthly summary of byproduct coke production will be issued by the U. S. Geological Survey according to the new plan recently adopted. Reports are requested from every coke-oven operator as soon as possible after the first of each calendar month for the output of byproduct coke during the previous month. Summaries of these reports will be prepared and issued as a portion of the weekly coal report of the Survey appearing in the number next following the 15th of the month succeeding that to which the data apply.

Federal Trade Commission Issues Order Against Royal Baking Powder Co.

Following inquiry, trial and final argument, the Federal Trade Commission on July 15, issued an order against the Royal Baking Powder Company to cease and desist from the sale or advertising for sale a phosphate baking powder under a label which simulates so closely as to be deceptive, a label long identified with a cream of tartar powder and from advertising price of the new powder as a reduction in price of the former product.

A competing concern complained against the Royal Baking Powder Company some months ago, charging unfair methods of competition. Testimony at trial of the case showed that the Royal Baking Powder Company in 1899 absorbed the company which manufactured and sold the well-known Dr. Price's cream baking powder, which had for its acid ingredient cream of tartar. At the trial it was shown that for a period of over sixty years prior to September, 1919, "Dr. Price's Cream Baking Powder" was marketed and advertised exclusively as cream of tartar baking powder, and that for at least thirty-five years the respondent and the Price Baking Powder Company carried on an extensive advertising campaign throughout the country to establish to consumers the superiority, especially from the point of view of healthfulness, of cream of tartar baking powder, and the inferiority of baking powders manufactured and sold by competitors which contained phosphate or alum or both as their acid ingredients. The latter competing powders were represented by the Royal Baking Powder Company in its advertising campaign to be unwholesome and deleterious.

It was further brought out in the testimony that in September, 1919, at a time when the price of cream of tartar was increasing the Royal Baking Powder Company after making certain alterations in its factory began the output of Dr. Price's baking powder substituting phosphate for cream of tartar as the acid ingredient of the commodity. It was shown also that coincidental with this change in the basic ingredients of the powder the Royal Baking Powder Company started a nation-wide campaign, advertising that the well-known Dr. Price's baking powder could now be bought by housewives for one half the price formerly charged.

This advertising campaign, it was shown by the testimony, misled the public into the belief that when it bought Dr. Price's baking powder it was buying the well-known cream of tartar brand for one half of what it formerly cost, when as a matter of fact it was buying a phosphate powder.

Standardization of Petroleum Specifications

A number of changes in the specifications used by the Federal Government for the purchase of gasoline, kerosene, fuel and lubricating oils were proposed at an open meeting of the Technical Committee on Standardization of Petroleum Specifications held at the Interior Department Building, Washington, D. C., on July 12. N. A. C. Smith, of the Bureau of Mines and chairman of the committee, presided. Representatives of the different government departments and members of the technical staffs of the various refining companies were present. The several engineering societies constituting the Advisory Board were represented by the chairman of the board, Dr. T. G. Delbridge, of the American Society for Testing Materials and the American Petroleum Institute.

The new methods of testing various petroleum products, which have recently been approved by the American Society for Testing Materials, were discussed, and although the general sentiment of the meeting favored their adoption, it was decided that careful study should first be given to each method. The methods discussed included the following tests: corrosion; flash; distillation; sulphur; cloud and pour; saponification in place of fatty oil; water and sediment, precipitation; viscosity, and melting point.

Considerable discussion arose over the distillation range of motor gasoline. It was suggested that the present 90 per cent point should be raised slightly. On the other hand,

it was argued that the specification should be retained unchanged until such time as an entirely new grade of gasoline can be used. It was said that experimental work now in progress would probably afford more information as to the correct range for motor gasoline.

In view of the fact that the specification for fuel oil for Diesel engines, which had been intended to cover a very high grade of oil for submarines, has been criticised as being too stringent, a revision of the fuel oil specifications was proposed to show how several of the present grades can be used for Diesel and other oil engines. The raising of the permissible water and sediment from 1 to 2 per cent was advocated with the penalty attached for all water and sediment above one per cent. It was shown that testing the viscosity of fuel oils at 77 instead of 70 deg. F. would be in harmony with the work of the American Society for Testing Materials.

Other subjects discussed included the proper application of the saponification number of fatty oils, more definite color standards and a corrosion test for gasoline, and the need for further definiteness in the test for the emulsifying properties of lubricants.

At the close of the meeting Chairman Smith announced that he would tabulate the various suggestions made and would, within a short time, call a meeting of the Technical Committee to vote on the final form of the revisions, which would then be submitted to the Interdepartmental Committee for approval and publication.

The Committee on Standardization of Petroleum Specifications, frequently known as the Presidential Committee, was a war-time committee originally under the direction of the Fuel Administrator but later transferred to the Bureau of Mines. Bulletin 5 was its last official publication, and contained all of the committee's testing methods and specifications in their latest revised form. This war-time committee went out of existence on January 18 of this year, when the President authorized the Secretary of the Interior to form a new Interdepartmental Committee on Standardization of Petroleum Specifications.

The new committee met and organized on February 19 and adopted Bulletin 5 pending its revision. Each member of the committee appointed a technical representative, and these representatives were directed to form a Technical Committee to consider the revision of Bulletin 5 and to make recommendations in the matter to the Interdepartmental Committee. This plan was used successfully by the previous committee. The Technical Committee has met twice and has compiled a list of suggested changes and additions to Bulletin 5. Neither committee has yet voted on these proposals, but it is now planned to compile them in final shape and the Technical Committee will then decide what recommendations it will make to the Interdepartmental Committee.

The original committee tried to maintain as close contact as possible with the various industries involved in the manufacture and use of petroleum products. To make this contact even more effective the Interdepartmental Committee authorized the formation of an Advisory Board composed of representatives of the several engineering societies interested. This board met with the Technical Committee on May 4, and appointed Dr. T. G. Delbridge, representing the American Society for Testing Materials, as chairman. It is hoped that the Advisory Board will serve to bring to the attention of the committee such changes in the specifications as may become necessary from time to time, and that it will also be able to aid the committee by making available the technical knowledge of the refiners and of the consumers of petroleum products.

Canadian Chicago Bridge & Iron Co. Changes Name

The Canadian Chicago Bridge & Iron Co., Ltd., of Bridgeburg, Ontario and Montreal, Quebec, has changed its corporate name to the Horton Steel Works, Ltd., in honor of the late Horace E. Horton, who founded the organization in the United States in 1865. The Canadian organization was first incorporated in 1913, the plant at Bridgeburg being constructed in that year.

Chemical Exposition Notes

DRIERS AND EVAPORATORS

The services of expert drying engineers from experimental drying laboratories will be at the disposal of any interested visitor at the Seventh National Exposition of Chemical Industries to be held in the Eighth Coast Artillery Armory, New York, Sept. 12 to 17. The discussion of all problems in connection with satisfaction and economy in drying products is urged by all exhibitors.

Exhibits on this subject will include a one-man machine that dries any material capable of being sprayed in three seconds, and to pass practically any mesh desired without scorching or burning, a vacuum chamber drier which dries sensitive materials which are subject to reaction, oxidation, discoloration, etc., at a high temperature, without any of these changes taking place, vacuum drum driers so constructed that every part is readily accessible, enabling the drier to be kept sanitary at all times, in fact every phase and condition of drying systems will be covered designed to eliminate all excess of consumption of steam, grinding costs, time, labor, and floor space.

Something new will be displayed in the nature of an evaporator, which will be featured by one exhibitor. This evaporator has been developed by long experience in the evaporator field. The heating tubes are neither horizontal nor vertical. They are installed in an angle position and are staggered. Steam enters the top chamber on left hand and descends through the tube toward the right. Any condensation formed falls to the bottom and goes out the pipe provided for this purpose. The steam which is not condensed rises and again descends through the tubes toward the left. This inclination of the tubes very materially increases the flow of the steam through the unit and consequently gives a very large capacity per sq.ft. of heating surface. Well directed and very violent circulation of the liquid being evaporated is one of the features of the machine, while a large expanding chamber above the heating surface has been provided.

How to turn waste liquors from a variety of chemical industries and convert noxious waste elements into a dry, compact, odorless and frequently valuable byproduct is one of the interesting subjects which will be discussed. In fact the exposition offers the technical and engineering service of the most experienced chemical engineers to visitors seeking a solution to such problems.

Petrolia Helium Plant Shut Down

Orders have been issued to reduce the staff at the Government Helium Plant No. 3 at Petrolia, Texas, and to place the heavy machinery in standby condition for the present. These orders, issued by H. Foster Bain, director of the U. S. Bureau of Mines, have been concurred in by the U. S. Helium Board, composed of representatives of the Army, Navy and Bureau of Mines.

The extreme lack of funds necessary for the continuance of the plant and the desire to reduce to an absolute minimum the present expenditures of the Government have caused officials of the Bureau of Mines, which is immediately in charge for the Army and Navy, to feel that a stage has been reached where it will be better to work with a smaller unit while accumulating the data necessary for conversion into an economical operating plant, rather than to attempt steady operations with machinery planned primarily for experimental work. This plant was built in war time to test out the Jefferies-Norton process for separation of helium from natural gas and has since been operated intermittently on an experimental basis.

It is felt by the officials of the bureau that it is possible to place the Petrolia plant in a standby condition, since the large production plant at Forth Worth, operated by the Navy, is in operation. Both plants have been drawing on the same supply for gas and it will simplify the operations of the Lone Star Gas Company, which produces it, to have Plant 3 held in reserve while the Forth Worth plant is being brought up to full scale steady operation, since success is contingent upon a steady flow of gas of fairly uniform composition.

Plant No. 3, while undergoing trials, has produced helium

of 60 per cent purity and has made repeated runs of considerable duration, yielding gas of lower purity. While by re-processing, it is possible to bring up such gas to the standard for balloon use, this would increase the cost and it has been the expectation of the Bureau of Mines that first run gas of satisfactory purity could be obtained. As a war measure, it was considered wise to build on a sufficient scale so that the experimental plant could be transformed directly into an operating unit, but with the close of the war and the completion at Forth Worth of a production plant which, to a certain extent, meets present needs, it is more economical to conduct the experimental work on a smaller scale.

The purpose of continuing it is to provide ultimately a plant which shall furnish helium at a much lower cost than is possible by any known operative system. The importance of having a supply of non-combustible balloon gas in war time, and its utility in times of peace is so great that it is necessary that every means of reducing the cost be fully studied.

American Foundrymen's Association Postpones Convention

From the date of organization to 1911 the conventions of the American Foundrymen's Association were held in May or June of each year. In 1912 it was found necessary to postpone the convention scheduled for June at Buffalo until late in September, due to delay in completing the building in which the exhibits were to be placed, and since that time the annual meetings have been held in the fall.

When the committee met this year to consider the place of the next meeting it was found that in none of the eight cities considered was it possible to find, during September or October, adequate hotel accommodations and exhibit facilities to properly care for such meetings as were held in 1919 and 1920.

Confronted with this situation and taking into consideration general industrial conditions, the committee adopted a resolution recommending to the board of directors that the convention be held in New York City, in October or November of this year, without exhibits. After due consideration it was decided to hold the next convention and exhibit in April or May, 1922, at a place to be selected by the convention and exhibits committee.

With the hotels disposed to reserve a larger percentage of their rooms for a convention in the spring than in the fall, and with the probability that better exhibition facilities can be secured in the spring of 1922, it is hoped that no difficulty will be experienced in making satisfactory arrangements for the next convention and exhibit, the place and date of which will be announced later.

New Chemical and Oil Companies

During the month of June a total of 18 new chemical concerns were organized, with an authorized capital of \$50,000 or over, and aggregate capitalization of \$3,325,000. In a same month a year ago, the combined capitalization of companies formed in that month was \$41,476,000. This month has produced the lowest point yet recorded for 1921. For the first six months of the year, the total capital represented by new companies in the chemical field is \$65,625,000. Of this aggregate, January was the largest month, with an amount of \$22,295,000; the other months totaled: February, \$6,450,000; March, \$11,765,000; April, \$9,390,000; May, \$12,400,000, and June, as noted, \$3,325,000.

During the same month, a total of 65 oil companies was formed, with aggregate capitalization of \$52,620,000, each company being capitalized for \$50,000 or more. This is the lowest month of the present year and compares with June, 1920, with a total of 132 companies, and combined capitalization of \$161,275,000. During the first six months of the present year, a total of 545 companies in this line has been organized, with aggregate capitalization involving \$812,280,000. The largest month was April, representing \$227,470,000 in combined capitals of new companies. The other months were: January, \$163,480,000; February, \$136,935,000; March, \$148,850,000; May, \$112,925,000; and June, as noted, \$52,620,000.

The Paper Industry in the Kalamazoo Valley District

There are 18 paper manufacturing companies in the Kalamazoo Valley district of Michigan, with stockholders in the different concerns totaling close to 2,000, the large majority of whom reside in this same section. Following unusually prosperous times, when large stock and cash dividends were declared, the industry is now passing through a period of curtailment. During the past 3 months the wages of employees have been reduced from 46 per cent to about 30 per cent at the different mills, and in this same period stockholders have sustained dividend losses ranging from 25 per cent upward.

C.W.S. Needs \$4,000,000 Next Year

To carry on the work of the Chemical Warfare Service during the next fiscal year on a scale necessary to insure the proper development of that arm of the military service, Congress should appropriate not less than \$4,000,000 in the opinion of chemists who are familiar with the work of the service. This is exclusive of the expense which would be required for the production of masks or other equipment. It is declared that the work on war gases is at a stage of development which requires intensive application on a variety of chemical and mechanical problems, if practical use is to be made of the more recent developments in this work.

Book Reviews

IRON AND STEEL IN SWEDEN. A compilation by *Alf Grabe*. Edited and Published under the control of and in co-operation with Jernkontoret. 183 pp., 7½ x 9½ in. New York: The Swedish Chamber of Commerce of the United States.

This well made book is frankly a piece of propaganda aimed at giving correct information regarding irons, steels and their major manufactures available for export. A list of producing firms is given under each class of material, together with post office and telegraph address, code, and export harbor. A good map is also included.

About one quarter of the hundred Swedish iron and steel firms are described in detail, and herein lies the main interest of the book to metallurgists. The equipment and plant of such well known companies as Udderholm, Bofors, Sandriken, Osterberg, Avesta, and Hellefors are described. Particularly fascinating are the historical notes, nearly every one of the operations having its beginnings centuries back.

* * *

THE CHEMISTRY OF PLANT LIFE. By *Rosecoe W. Thatcher*. 268 pages. New York: McGraw-Hill Book Co., Inc. Price, \$3.

The author states in the preface that he had in mind a two-fold purpose in the preparation of the book which bears the above title.

First, it is hoped that it may serve as a reference book for collegiate students of plant science who are seeking a proper foundation on which to build a scientific knowledge of how plants grow.

Second, the purpose of the writer will not have been fully accomplished unless the book shall serve as a stimulus to further study in a fascinating field.

The chapter headings which follow give an idea of the scope of the work:

Introduction; Plant Nutrients; Organic Components of Plants; Photosynthesis; Carbohydrates; Gums, Pectins and Celluloses; Glucosides; Tannins; Pigments; Organic Acids; Acid Salts and Esters; Fats and Oils, Waxes and Lipoids; Essential Oils and Resins; The Vegetable Bases; Proteins; Enzymes; The Colloidal Conditions; The Physical Chemistry of Protoplasm; Hormones, Auximones, Vitamines, and Toxins; Adaptations; Index.

The book seems, to the reviewer, to be a chemistry of substances which occur in plants rather than a chemistry

of plant life. It contains in its various chapters excellent discussions of the chemical properties of various important plant substances such as sugars, glucosides, fats, proteins, pigments, etc. There is, however, relatively little on the living chemistry of these compounds. Each chapter closes with a discussion of the physiological uses of and the biological significance of the compounds discussed in that chapter. This discussion is necessarily limited in most cases by the meagreness of our knowledge of the chemistry of living processes. These chapter discussions in many cases suggest various avenues of investigation for the research student. In this Dean Thatcher has accomplished his second purpose admirably. The book should also go far toward accomplishing the first purpose since a knowledge of the laboratory chemistry of those compounds which occur in plants is important for an understanding of plant problems.

Dean Thatcher's book supplies a long-felt want since it is the first book of this kind from the pen of an American scientist who is a recognized authority in this field. "The Chemistry of Plant Life" should prove useful to a large number of students, either as a text or reference work. The book is well gotten up and is interestingly written. A few errors such as usually creep into a first edition were noted. For example, the formulas of some of the sugars and glucosides are incorrectly printed.

FRED W. UPSON.

Personal

Dr. CARL L. ALSBERG, formerly chief of the Bureau of Chemistry, has left Washington, D. C., for Stanford University, where he will have the directorship of the food research institute of Leland Stanford University. Dr. Alsberg's successor has not yet been appointed.

W. H. BASSETT, technical superintendent of the American Iron Company, has been elected chairman, and G. C. Stone, metallurgist of the New Jersey Zinc Co., secretary, of a committee on zinc and zinc ores, recently organized by the American Society for Testing Materials, to work in co-operation with the American Zinc Institute.

ARTHUR M. COMEY, director of the Eastern Laboratory, E. I. duPont de Nemours Powder Co., has resigned and will reside in Cambridge, Mass. He expects to devote his time to writing.

C. D. DAVIES has been appointed managing editor of *Mechanical Engineering*, which is published by the American Society of Mechanical Engineers, succeeding the late L. G. French.

M. V. DISHER has become president of the Bertie Natural Gas Co., Ltd., Ridgway, Ont., succeeding John Young.

Dr. FEDERICO GIOLITTI is planning a brief business trip to America in a few months.

R. C. PURDY, consulting ceramic engineer, at Columbus, has been appointed chairman of the committee C-S of the American Society for Testing Materials for the study of refractories.

OTTO W. SIEBERT, Gardner, Mass., for the past twenty-three years secretary and treasurer of the Bay State Metal Wheel Co., and the Children's Vehicle Corporation, both of East Templeton, Mass., has disposed of his interest in these companies to devote his entire time to the American Fiber Co., of which he is an officer and large stockholder.

E. C. WELBORN, 29 South La Salle St., Chicago, has opened offices as business and engineering counsel in the solution of financial, business and engineering problems. He was formerly identified with the Illinois Steel Co., the Allis-Chalmers Mfg. Co., the Standard Separator Co. and for the past two years has been vice-president of the Hanna Engineering Works, Chicago, in charge of engineering development, manufacturing and sales.

C. D. YOUNG was elected president of the American Society for Testing Materials at the recent annual meeting held at Asbury Park, N. J.

Obituary

Major LOUIS A. FISCHER, chief of the Division of Weights and Measures of the Bureau of Standards, died at his home in Washington July 25, at the age of 57. Major Fischer had been in charge of that division of the Bureau's work since its foundation in 1910. Prior to that time, he served for many years in the old Weights and Measures office of the Coast and Geodetic Survey. Major Fischer obtained his title during the war, when he was commissioned to carry forward important work for the Ordnance Department. He was in immediate charge of the section of gage design.

EDWARD HARTNESS KIDDER, 82 years old, one of the founders of The Barrett Co., N. Y., died July 22.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, July 29, 1921.

There was a slight improvement noted in the volume of chemical transactions during the past week, but no apparent snap to trading was visible. Quiet intervals are to be expected during this time of the year. Interests close to the pulse of business are convinced that the market is diverging from the course it seemed headed for and that it is gradually rounding itself into good shape. That the peak of depression has passed is the general belief of some of the largest manufacturers as well as dealers. The trend of chemical values has been downward since the beginning of the year, but prices in the more important commodities are showing more resistance at present. This condition is to be expected because there are no flagrant signs of forced selling while indications favor stability after a period of liquidation experienced for so many months. No one is looking for a sharp recovery in the general list although some items with more speculative value than others will eventually follow the road of least resistance. It has been the desire of producers to stabilize the values all around and it looks as though their efforts will be successful. Price changes for the week have not been noticeable. *Bichromate of soda* has held well around former levels and the market is being watched on account of advices regarding the tanneries. *Caustic soda* has been somewhat lower in the resale market while light *soda ash* has met with support at recently quoted prices. Contract prices on both of these latter items have not been altered in the open market. *Bleaching powder* has found buyers in the paper-making industry. *Prussiate of soda* eased off slightly under the competitive attitude of sellers. *Nitrite of soda* was also a shade easier. Domestic *oxalic acid* has been well sustained while small lots of imported material have moved at concessions. Some interests believe that *mariate of potash* is due for a rise while others do not anticipate any nearby change. *Sulphuric acid* is moving quietly at old figures. Leading producers of *copper sulphate* say that June sales to the agricultural trade exceeded all previous records. *Camphor* has ruled steady and a little firmer feeling was reported.

EXPORT OUTLOOK IMPROVING

According to those well posted in foreign affairs, the export outlook is gradually improving. Throughout the European continent, except Russia, conditions are steadily progressing, although the disordered state of public finances continues to be a heavy handicap to industry. German competition in the world market is favored by the position of the mark, but, on the other hand, continued inflation of the German currency, after inflation has practically ceased in

other countries, is serving to maintain German production costs, including labor, while they are declining in other important centers. Though the Russian situation imposes a severe detriment on European recovery, it is also to be remembered that Russia has been practically cut off from Europe for several years and business has become accustomed to do without Russia. In the European situation there are also indications of a steadying of political conditions and of a better attitude of the respective nations toward each other, which are of especial significance. A restoration of political stability must in a large measure precede Europe's economic rehabilitation. From the Far East we learn that conditions in India and China are clearly, even though only slightly, better, despite the position of silver and uncertain political factors in both countries. Improvement in Japan is plainly indicated by the improvement in the bank situation. The less developed countries, those chiefly dependent on an export market for raw materials, are at this time in the least satisfactory condition. Reviewing the world situation as a whole, for the first time since the armistice there is a sound basis for a hopeful outlook.

CHEMICALS

Bichromate of potash is finding a quiet outlook at 11½@11¾c. per lb., depending upon the quantity. Small resale lots have changed hands at 11¾@12c. Odd lot sales of calcined *carbonate of potash*, 80-85 per cent, are reported at 5½c. per lb. It is very possible that this price could be shaded on a firm offer for a round lot. The 90-95 per cent is obtainable at 6c. per lb. The inquiry is not very active and the movement is confined chiefly to small quantities. Imported *caustic potash*, 88-92 per cent, is moving quietly at 4¾c. per lb. and upward, according to the size of order. Some business in this material has been booked lately while soapmakers and dealers report the market quite steady at recently quoted figures. *Standard bichromate of soda* on spot is reported firm at 8c. per lb., with light trading reported at 8@8¼c. As previously stated, offerings are not heavy and it is doubtful if much material could be purchased without advancing quotations. Producers of *bicarbonate of soda* quote the market on a basis of 2¼c. per lb. in bbls. and 2½c. per lb. in kegs f.o.b. works. Sales of spot material have been reported by dealers at \$2.40@\$2.50 per 100 lb. in bbls. ex store. Resales of solid *caustic soda* have been reported at slightly lower prices although there is no sign of real weakness in the market. Producers quote the market firm at 3¼c. per lb., basis 60 per cent f.o.b. works and 5c. per 100 lb. higher for single carload lots. Dealers quote the market at \$3.85@\$3.90 per 100 lb. for standard goods either ex store or f.a.s. N. Y. Moderate miscellaneous inquiries are reaching the market but business in most quarters appears rather quiet.

Producers of *fluoride of soda* are reporting sales of this material at 12c. per lb. ex store. Prices in the open market range from 11½@13c. per lb. While rumors of odd lots of *nitrite of soda* have been heard at slight concessions, sellers were not inclined to quote under 7c. per lb. for spot material in the resale market. The general quotation was 7@7¼c. per lb., depending on quantity and seller. Imported *prussiate of soda* is quoted at 11½c. per lb. for shipment and spot quotations were heard at 11½@11¾c. per lb. The competitive attitude of sellers is responsible for the recent decline of values. Imported *sulphide of soda*, 60-62 per cent, fused, was offered at prices ranging from 4¾@5c. per lb. The broken variety is held at 5½@6c. per lb., depending on seller and quantity. Spot offerings did not appear to be unusually free, but it was stated that goods are expected within the next few days.

Prices on spot *citric acid* range from 44@45c. per lb., with most sellers not eager to shade 44½c. Small lots are attracting some attention and the movement is mostly of a jobbing character. Manufacturers of *hydrofluoric acid* are offering the 30 per cent test at 7c. per lb. in bbls. and report some business at this figure. The 48 per cent test is quoted nominally at 10c. per lb. and the 52 per cent at 11½c. per lb. Sales of *formaldehyde* are reported at prices ranging from 12½@13c. per lb., depending upon the seller. The demand is quiet and aside from the exchange of a few

moderate quantities the movement has been devoid of any special features. Dealers of *epsom salt* report sales of the technical variety at \$1.20@1.50 per 100 lb., according to the quantity. The U.S.P. variety is held at \$2.40@2.60 per 100 lb. in carload lots and up to 3c. per lb. in smaller quantities. American *oxalic acid* is quoted at 17½c. per lb. f.o.b. works and at various figures up to 19c. per lb. on spot, depending upon seller and quantity. Small lots of imported material are quoted at 17½@17¾c. per lb., with occasional odd lot sales down to 17¼c. per lb. The inquiry for *sulphate of aluminum* was reported more active in some quarters and it was stated that the consuming trade was showing more interest. Sellers quoted the iron-free variety at 3@3½c. per lb. and the commercial at 2@2½c. per lb. Producers of *acetic acid* have slightly strengthened their views on the different grades. While it is possible that 2½c. might be done in a large way in the 28 per cent, commercial, first hands are not inclined to quote below 2¼@3c. per lb. The 56 per cent test is quoted at 5@6c. and the glacial 99 per cent is moving quietly at prices from 10@10½c. per lb., according to seller.

The inquiry for *copper sulphate* for agricultural requirements still continues active and considerable business is being placed by leading producers. In one prominent selling quarter it was stated that June sales to farming sections were the best ever recorded. Textile mills are showing more interest and some business is being recorded. The increase in sales is quite large compared with a few months ago. Export inquiries are reaching the market but little actual business is being placed. Leading producers quote 5¾c. per lb. for standard 99 per cent large crystals and up to 6c. per lb. for less than carload lots. Small crystals, 98-99 per cent, is quoted at 5½c. per lb. in carlots and ¼c. per lb. higher for smaller quantities.

COAL-TAR PRODUCTS

Leading producers of coal-tar products are firmly maintaining prices on their stocks. Some weak producers on the other hand are shading prices and holders of high priced resale goods are cutting prices. Surface conditions in the trade are rather spotty, but the undertone is surprisingly strong. One of the leading figures in the market states that in his opinion good business can be looked for at the beginning of the fall season and that in the meantime a steady improvement will be made in the volume of sales. Some producers report very favorable business over the past month, with consumers showing an increased tendency to buy ahead. On some products there undoubtedly will be further price reductions and liquidation of weak holdings may cause price flurries, but on the whole, consumers, by their recent steady buying are testifying to their faith in the stability of prices on many items. The export demand for *benzene*, particularly from England, continues strong, but supplies are limited and most of the orders remain unfilled. Domestic consumers have to be satisfied with future deliveries. Producers are firm at 27@33c. per gal. for the pure grade. *Naphthalene flakes* are easy with the demand rather light. Prime white flakes are quoted at 6¾c. per lb. and off-colored can be had down to 4c. per lb. Balls are around 8@8½c. per lb. in the resale market. Producers of *toluene* quote lower prices than resellers, but it would be difficult to obtain a round lot from other than first hands. The demand is fairly strong, but the light supply keeps the price pegged at 28c. per gal. and up, depending on quantity. Some fair sized lots of *aniline oil* sold at 18c. per lb. Other sellers ask up to 21c. The demand is light, but some routine business is passing. Surplus stocks of *beta-naphthol* are making prices saggy and the low figure of 33c. per lb. could easily be shaded on real business. Inquiries were heard at prices below the above figure. Some sellers asked up to 36c. per lb., but buyers are uninterested at the high level. Lower prices on *paranitraniline* have stimulated buying to a fair extent. Quotations range from 75@85c. per lb. Light business passed in *para-phenylenediamine* at \$1.70 with quotations ranging up to \$1.80. More interest was displayed at the close of the week. Small lot business in *benzidine sulphate* passed at 75c. per lb. The base variety held at 85c., with some sellers asking up to 90c. per lb.

The Chicago Market

CHICAGO, Ill., July 29, 1921.

Developments of importance were lacking in the industrial chemical market during the past week. Dealers report a good volume of small orders but nothing in the way of large business was noted. As a rule prices were quite firm with little or no shading. Stocks are getting smaller and practically all distressed material has been absorbed.

Caustic soda is firm and quiet with supplies light. The solid 76 per cent is quoted at \$4@4.10 per 100 lb. and the ground or flake at \$4.65. *Soda ash* is moving in a very fair way and in some quarters stocks are getting low. The prevailing quotation was \$2.60 per 100 lb. in bbls., although it was possible to shade this price slightly in some directions for quantities. *Ammonium chloride* is quiet and unchanged as to price, supplies being readily available at 7½c. per lb. for the white granular. Spot stocks of *barium chloride* are offered freely at \$75@385 per ton according to the quantity. *Copper sulphate* is moving in a small way at 6¼c. per lb. for less than car lots. The demand for *carbon tetrachloride* has dropped off somewhat but the price is firm at 11c. per lb. *Carbon bisulphide* is in better request and supplies are available at 6¾@7c. per lb. *Formaldehyde* is dull and plentiful at 14c. per lb. in single bbl. lots. There is a fair movement of methanol 95 per cent at 75c. per gal. in drums. *Glycerine* is very quiet with plentiful supplies of the C.P. available at 14¾c. per lb. There is a fair demand for *iron sulphate*, holders asking \$1.90 per 100 lb. for bbls.

A quiet market continues to be noted for *potassium bichromate* and the situation lacks new features of any kind. Buyers are interested only in small quantities and the price is unchanged at 14½@14¾c. per lb. *Sodium bichromate* is in the same position and supplies are available at 9@9½c. *Caustic potash* is quiet, dealers asking 6½@6¾c. per lb. for the 88-92 per cent material. A fair movement of *bicarbonate of soda* was noted at \$2.65 per 100 lb. *Hyposulphite of soda* continues to move in a small way to the photographic trade and dealers are asking \$4.05 per 100 lb. for the pea cryst. in bbls. *Zinc chloride* is moving in a small way and holders are asking 11@11½c. for spot goods.

There were no new developments in the acid markets during the past week, the prevailing tone being firm. The 28 per cent *acetic acid* continues to move fairly well and the price is unchanged at \$2.60 per 100 lb. for bbls. Glacial *acetic* is extremely quiet, some quarters reporting no sales. A wide range of prices are obtainable running from 8 to 11c. per lb. A brisk demand for *oxalic acid* was noted and the price is very firm at 18c. per lb. for bbls. The heavy acids are all quiet and unchanged in price. *Hydrochloric* is offered at 1¾@2c. per lb. in carboys.

VEGETABLE OILS

Linseed oil is the item demanding the most attention in this branch of the trade. This material is quoted higher at 81c. per gal. for the raw and 83c. for the boiled. Dealers report a good movement to the paint trade and appear to be well satisfied.

NAVAL STORES

Business in the naval stores market continues good and all quarters report a satisfactory volume. *Turpentine* is moving in a very fair way at 66½c. per gal. Business on the *rosins* is better and the G grade is quoted today at \$5.50 per 280 lb. in car lots. *Rosin oils* are not moving so well and the spot price is unchanged at 45c. per gal. for material in cooperage.

The Iron and Steel Market

PITTSBURGH, July 29, 1921.

The turn in the tide as to the volume of demand upon the steel mills, only barely perceptible at the time of last report, has now become more clearly marked. Beginning in sheets the improvement has spread over bars, tubular goods and probably some other products. In no case is there any sweeping change, there being merely a gradual increase in the total volume of tonnage. Buying or specifying in large lots is conspicuously absent, engagements for moderate sized lots are few, and single carload orders and specifications are impressively numerous.

The totally wrong inference is drawn in some quarters that buying is being encouraged, business is being developed, by declining prices. Scrutiny of the business placed shows plainly that this is not the case. Steel prices are declining, but reduced prices are not made on the principle of encouraging buyers to buy. It might even be said that a mill does not reduce a price to bring the order to it, but rather to forestall its going elsewhere. That is, nearly every order or specification results from a determination of the buyer to buy, and buy at once. If there is negotiation, it is merely to determine where the order is to be placed, and at what particular price.

Practically all the increase in buying and specifying is attributable to further depletion of stocks, in the hands of jobbers and manufacturing consumers. Thus, instead of there being indicated any material increase in actual ultimate consumption of goods made from steel there is indicated rather a trend in demand upon the mills toward a rate in keeping with the present level of general industrial or commercial activity. For some time past the demand upon the mills has been subnormal in this relation.

PRICES DECLINING

While no formula can be devised to represent the rate at which steel prices have been or are declining, it may be said, very roughly speaking, that the average of all steel mill products has been going down in the past few weeks at the rate of something like a dollar per net ton per week. If precisely such a rate were maintained for a weighted average of the various commodities the average would be down to zero in about a year. The illustration may be fanciful, but it furnishes an idea of what has been occurring. Steel prices now, by a weighted average, are about \$15 per net ton above the ten-year pre-war average and about \$23 above the extreme low point, touched at the end of 1914. Considering the great increases in production costs there is no room left for an actual "break" in steel prices, but apart from that consideration, the market is too soft to break. The analogy between the market and a material is inexact only in that softness is a greater preventive of breakage in a market than in a material.

In last report reference was made to a recent trend in prices toward wider spreads between large lots and small lots. In the past week the trend has rather been the other way, of prices showing less variation according to the tonnage involved. What was the large lot price of two or three weeks ago may be the carload price now, but the large lot price has not declined as much as the carload price.

The independent market on bars, shapes and plates has tended to crystallize on prices of 1.75c. for bars and 1.85c. for shapes and plates, for carloads and moderate sized lots, with possibly slight concessions in some cases for large lots. As to Pittsburgh territory the Steel Corporation retains 1.90c. on bars and 2c. on shapes and plates as its regular prices, although it is possible concessions might be made. In territory removed from Pittsburgh the "Pittsburgh plus" system has disappeared very largely in substance, though the form may remain, by the necessity of meeting independent competition, particularly in Chicago territory.

The common market on sheets is 3.25c. for black and 4.25c. on galvanized, or \$5 a ton below the prices announced July 5, but the lower prices here named might be shaded in some cases.

OPERATIONS

There has been an increase in mill operations, on the whole, in the past fortnight, but the average rate of operation of the industry cannot be estimated closely enough to show the change. Steel production is probably at about 20 per cent of capacity. Rates are quite different in different lines. Sheets are being produced at perhaps 30 per cent of capacity, tubular goods coming next. Rail production is almost zero. The most conspicuous case of improvement is that of sheet mill operations by the Steel Corporation, which were a shade under 30 per cent week before last and about 36 per cent last week, while an average of about 40 per cent is likely to mark the present week.

Naphthalene, flake..... lb.	.06 - .08
Naphthalene, balls..... lb.	.08 - .09
Naphthionic acid, crude..... lb.	.70 - .75
Nitrobenzene..... lb.	.12 - .15
Nitro-naphthalene..... lb.	.30 - .35
Nitro-toluene..... lb.	.16 - .18
Ortho-amidophenol..... lb.	3 10 - 3 20
Ortho-dichlor-benzene..... lb.	.15 - .20
Ortho-nitro-phenol..... lb.	.80 - .85
Ortho-nitro-toluene..... lb.	.15 - .20
Ortho-toluidine..... lb.	.20 - .25
Para-amidophenol, base..... lb.	1 40 - 1 45
Para-amidophenol, HCl..... lb.	1 60 - 1 75

Para-dichlorobenzene..... lb.	15 - 20
Paramethaniline..... lb.	75 - 80
Para-nitrotoluene..... lb.	45 - 50
Para-phenylenediamine..... lb.	70 - 75
Para-toluene..... lb.	25 - 30
Phthalic anhydride..... lb.	30 - 35
Phenol, U. S. P., drums..... lb.	20 - 25
Pyridine..... gal.	2 00 - 3 50
Resorcinol, technical..... lb.	1 40 - 1 45
Resorcinol, pure..... lb.	2 25 - 2 30
Salicylic acid, tech., in bbls..... lb.	20 - 22
Salicylic acid, U. S. P..... lb.	23 - 25
Salol..... lb.	41 - 45
Solvent naphtha, water-white, in drums, 100 gal..... gal.	25 - 28
Solvent naphtha, crude, heavy, in drums, 100 gal..... gal.	24 - 26
Sulphanilic acid, crude..... lb.	30 - 35
Tolidine..... lb.	25 - 35
Toluidine, mixed..... lb.	40 - 45
Toluene, in tank cars..... gal.	25 - 28
Toluene, in drums..... gal.	28 - 31
Xylidines, drums, 100 gal..... lb.	40 - 45
Xylene, pure, in drums..... gal.	40 - 45
Xylene, pure, in tank cars..... gal.	45 - 48
Xylene, commercial, in drums, 100 gal..... gal.	33 - 35
Xylene, commercial, in tank cars..... gal.	30 - 32

Waxes

Prices based on original packages in large quantities

Beeswax, refined, dark..... lb.	\$0 24 - \$0 25
Beeswax, refined, light..... lb.	27 - 28
Beeswax, white pure..... lb.	40 - 45
Carnauba, Florida..... lb.	58 - 60
Carnauba, No. 2, North Country..... lb.	25 - 26
Carnauba, No. 3, North Country..... lb.	13 - 14
Japan..... lb.	15 - 16
Montan, crude..... lb.	00 - 00
Paraffine waxes, crude match wax (white) 105-110 m.p..... lb.	03 - 03
Paraffine waxes, crude, scale 124-126 m.p..... lb.	02 - 02
Paraffine waxes, refined, 118-120 m.p..... lb.	03 - 03
Paraffine waxes, refined, 125 m.p..... lb.	03 - 03
Paraffine waxes, refined, 128-130 m.p..... lb.	04 - 04
Paraffine waxes, refined, 133-135 m.p..... lb.	04 - 05
Paraffine waxes, refined, 135-137 m.p..... lb.	05 - 06
Stearic acid, single pressed..... lb.	09 - 09
Stearic acid, double pressed..... lb.	09 - 09
Stearic acid, triple pressed..... lb.	10 - 10

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl..... 280 lb.	\$5 10 - 5 15
Rosin E-L..... 280 lb.	5 20 - 5 45
Rosin K-N..... 280 lb.	5 70 - 6 75
Rosin W. G.-W. W..... 280 lb.	7 35 - 7 40
Wool rosin, bbl..... 280 lb.	6 25 - 6 30
Spirit of turpentine..... gal.	59 - 59
Wood turpentine, steam dist..... gal.	57 - 57
Wood turpentine, dest. dist..... gal.	55 - 55

Plates, ½ to 1 in. thick.....	2.18	3.00	3.00

*Add 15c per 100 lb. for trucking to Jersey City and 10c for delivery in New York and Brooklyn

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Arkansas

LITTLE ROCK—The Grandfield Refining Co., Kansas City, Mo., Garland Biffle, head of the company in charge, has plans under way for the establishment of a new branch oil refining plant at Little Rock, with initial capacity of about 5,000 bbl. Departments will be installed for the production of gasoline and naphtha. The new plant is estimated to cost about \$200,000 with equipment.

California

OXNARD—The Sierra Oil & Refining Co. has plans under way for the erection of a new local refinery to handle crude petroleum from the Camarillo-Conejo fields, in which the company is operating.

Delaware

WILMINGTON—The Atlas Powder Co., du Pont Bldg., has awarded a contract to the Austin Co., Bulletin Building, Philadelphia, Pa., for the erection of its proposed new 1-story experimental laboratory at Gray Street and Lancaster Avenue, to be 60x80-ft. The company has arranged for a bond issue of \$4,000,000 for general operations, financing, etc. W. J. Webster is president.

WILMINGTON—The Wilmington Sugar Refinery Co. has pile-driving and foundation work under way for the erection of its proposed new local sugar refining plant, to be 9-story, brick and steel, and estimated to cost in excess of \$2,500,000 with machinery. W. J. Wayte, Inc., Grand Central Terminal, New York, N. Y., is architect and engineer.

Florida

APOPKA—The Florida Insecticide Co. is perfecting plans for the construction of a new local plant, 46x50 ft., for the manufacture of insecticides and chemical specialties. J. C. Grossenbacher is manager.

Illinois

CHICAGO—The Waterway Paper Co., Kedzie Ave. and 32d St., has completed plans for the erection of a new 1-story plant on Kedzie Ave., 80x180 ft., estimated to cost about \$175,000, including power plant, 33x60 ft. Frank D. Chase, Inc., 645 North Michigan Ave., is architect and engineer.

RAYVILLE—The Hercules Powder Co., du Pont, Bldg., Wilmington, Del., is arranging for a number of improvements in its local dynamite plant, now inactive. It is proposed to resume operations at the works early in the fall.

Indiana

ALEXANDRIA—The Lippincott Glass Co. will make a number of improvements in its plant, including machinery repairs and betterments, during the remainder of the summer. The plant recently was closed down and will re-open early in the fall.

EVANSVILLE—The Graham Glass Co. is planning for the resumption of operations at its local plant at capacity early in September, concentrating on the production of bottles for beverages. Manufacture recently was curtailed with about 50 per cent of the regular working force.

Louisiana

SHREVEPORT—The Gulf States Chemical Co., has acquired the plant and adjoining property of the National Glass Co. The new owner will enlarge the works and make a number of improvements in present buildings for the manufacture of chemical specialties. Equipment will be installed at an early date. W. H. Raplee is vice-president.

NEW IBERIA—Fire, July 20, destroyed the refining plant of the Morshahn Sugar Co., with loss estimated at about \$250,000, including machinery and stock. It is reported that the plant will be rebuilt.

SHREVEPORT—The United States Window Glass Co., Morgantown, W. Va., is tak-

ing bids for the erection of its proposed new plant at Shreveport, to consist of a number of buildings, estimated to cost close to \$3,500,000 with machinery. The main glass works will be 1-story, 400x850 ft., with 3-story clay department, 80x140 ft. Other structures will include a power plant and box factory, the latter, 1-story, 100x200 ft. The DeVore Co., 908 Nicholas Bldg., Toledo, Ohio, is architect and engineer. Walter A. Jones is president. It is proposed to commence erection at an early date.

Maryland

CUMBERLAND—A number of former employees of the Wellington Glass Co. are in negotiation with Franklin H. Ankeney, secretary of the local Chamber of Commerce, for the rebuilding of the Wellington plant, destroyed by fire more than a year ago. It is proposed to re-establish the works, giving employment to close to 300 operatives.

Michigan

DETROIT—The Peninsular Paper Can Co., Detroit, is said to be planning for the establishment of a new plant at Monroe, Mich., for the manufacture of paper cans and other containers. It is proposed to inaugurate work at an early date, having the plant ready for service early in the fall. The company is arranging for a state charter with capital of \$500,000. R. P. Adams, sales manager of the Detroit Heating & Lighting Co., is president.

Missouri

OZARK—The Bain Mining Co. is perfecting plans for the construction of a new concentrating plant, electrically operated, with capacity of about 250 tons, at its local ore properties; the company has a tract of about 600 acres of land for development. John Denton, Ozark, is vice-president and construction engineer. Eastern offices of the company are at 925 Market Street, Wilmington, Del.

Nebraska

ANTIOCH—The Nebraska Potash Works has plans under way for the erection of new plant units to replace the portion of its plant recently destroyed by fire. The new buildings with equipment are estimated to cost about \$250,000.

Nevada

RENO—The Candelaria Mines Co. has approved plans for the erection of a new reduction plant at its silver properties in the Lucky Hill district. The initial cyanide unit will have a capacity of close to 200 tons of ore daily, while the crushing plant will be equipped for a production of about 400 tons per day. Eastern offices of the company are at 43 Exchange Place, New York, N. Y.

New Jersey

TRENTON—Milton Mirkens has acquired the former mill of the Ewing Rubber Co., Hilton Ave., for the establishment of a new plant for the manufacture of rubber goods. The structure will be remodeled at once and necessary machinery installed. The plant site totals 205x235 ft., providing space for future buildings.

NEWARK—Eric Steiner has leased the building in the rear of 52-54 Lafayette St., fronting on Maple Place, for the establishment of a new plant for the manufacture of colors, chemicals, etc., for the coloring of leather. Immediate possession will be taken and necessary equipment installed.

LINDEN—As soon as insurance has been adjusted, the Warner-Quinlan Asphalt Co., 79 Wall St., New York, N. Y., will commence the rebuilding of its plant at Linden, destroyed by fire July 18, with loss estimated at \$3,500,000, including equipment. In addition to the main manufacturing works, the loss included oil stills, oil tanks, asphalt tanks, gasoline tanks, machine shop and mechanical buildings, laboratory and power plant. Charles Almquist is superintendent.

GLASSBORO—The Owens Bottle Co. has started up one of the furnaces at its plant

at South Glassboro, following a curtailment of several weeks. Improvements and repairs are being made to the other furnaces at the plant, with plans to start up other units at an early date.

New York

ALBANY—A new 1-story foundry for the production of bronze and brass castings will be erected at the plant of the Thatcher Propeller & Machine Co., Learned St. The structure, with new machine shop to be built, is estimated to cost about \$150,000. George Thatcher is president.

BUFFALO—The Iroquois Natural Gas Co., Iroquois Building, has increased its capital from \$10,000,000 to \$11,000,000, the proceeds to be used for plant extensions and improvements. Bert C. Oliphant is president.

BROOKLYN—The Doshier Die-Casting Co., Court and Huntington Sts., has commenced the construction of a new gas manufacturing plant at its works to cost about \$40,000. The plant will be for exclusive plant service and is being constructed owing to the prevailing high rate for gas. Operation is estimated at 40c. per 1,000 cu.ft.

BUFFALO—The Archer-Daniels Linseed Co., Buffalo River, near Hamburg Turnpike, is said to be planning for the rebuilding of the portion of its plant destroyed by fire July 10, with loss estimated at about \$50,000, including equipment.

Ohio

YOUNGSTOWN—The Republic Rubber Corp. has resumed operations at its plant, following a suspension of several weeks, giving employment to about 700 operatives. Work will be conducted under the direction of H. C. Booth, receiver.

CLEVELAND—The Noble Refining Co., 706 Canal Road, has awarded a contract to the Camp Construction, Altamont Bldg., for the erection of its proposed new oil plant at East 99th St. and Elk Ave., estimated to cost about \$80,000. A power house will also be constructed.

Oklahoma

TULSA—The Constantin Refining Co., operating local oil refineries, has arranged for a bond issue of \$4,000,000 for improvements, extensions, general operations, etc. E. Constantin, Sr., is president.

Tennessee

MOUNT PLEASANT—The Phosphates Products Co., recently organized, is perfecting plans for the early erection of its proposed new local plant for the manufacture of fertilizer products. A number of plant departments will be installed, each for the purpose of manufacturing particular kinds of fertilizers.

Texas

HOUSTON—The Southern Brass & Plating Co. is planning for the rebuilding of the portion of its plant recently destroyed by fire.

West Virginia

MORGANTOWN—The South Penn Oil Co. is planning for extensions in its tankage department at a cost of about \$300,000. A number of new tanks, each with capacity of 74,000 bbl., will be installed.

HUNTINGTON—A new 1-story foundry, 50x120 ft., will be erected by the West Virginia Foundry & Stove Co., to be equipped for the manufacture of iron castings. It is proposed to double, approximately, the present plant output. Frank C. Boggess is manager.

Wisconsin

TOMAHAWK—The Tomahawk Steel & Iron Co. will take bids early in August for the construction of a new 2- and 3-story plant, 100x180 ft., to replace its works recently destroyed by fire. The new plant is estimated to cost about \$75,000. William Bauman is manager.

MILWAUKEE—The Filler & Stowell Co., 219-45 Beecher St., manufacturer of machinery, will make improvements and extensions in its 1-story foundry to cost about \$16,000. Walter Read is president.

Mexico

DURANGO—The Monterey Iron & Steel Co. is planning for the operation of its new iron ore properties at Iron Mountain, recently acquired, for raw material supply for its plant at Monterey, to be placed in active production at an early date.

Capital Increases, etc.

THE VITREOUS ENAMELING & STAMPING Co., 306 Depot Place, New York, N. Y., has filed notice of increase in capital from \$300,000 to \$400,000.

THE SUMMIT VARNISH Co., Summit, Ill., has filed notice of increase in capital from \$50,000 to \$100,000.

THE SOUTHERN OIL CORP., Tulsa, Okla., manufacturer of petroleum products, has filed notice of increase in capital to \$3,000,000.

THE MONROE BINDER BOARD Co., Monroe, Mich., manufacturer of paper board products, has filed notice of dissolution under state laws.

THE AMERICAN STEEL PRODUCTS Co., Macomb, Ill., has filed notice of increase in capital from \$100,000 to \$210,000.

THE CHAMPLAIN BRICK Co., Mechanicsville, N. Y., manufacturer of brick and other burned clay products, has increased its capital from \$40,000 to \$100,000.

THE CUMBERLAND HYDRAULIC CEMENT Co., Cumberland, Md., has filed notice of increase in capital from \$200,000 to \$450,000.

THE UNITED STATES MICA MFG. Co., Chicago, Ill., has filed notice of increase in capital from \$10,000 to \$50,000.

THE SUNBEAM CHEMICAL Co., 2436 West Fifteenth Street, Chicago, Ill., manufacturer of soaps, etc., has filed a voluntary petition in bankruptcy.

THE INDUSTRIAL POTASH CORP., Salt Lake City, Utah, has filed notice of decrease in capital from \$30,000,000 to \$16,000,000.

THE SUNSET PAINT Co., Los Angeles, Cal., has filed notice of increase in capital from \$100,000 to \$150,000. H. A. Hendriksen is secretary.

New Companies

THE SOUTH SANTA PAULA PETROLEUM Co., Los Angeles, Cal., has been incorporated with a capital of \$250,000 to manufacture petroleum products. The incorporators are Charles L. Horsey, Pioche, Nev.; W. H. Rand and Minor Moore, Washington Building, Los Angeles.

THE TIER CHEMICAL Co., 3920 Lake Park Ave., Chicago, Ill., has been chartered under state laws to manufacture chemicals and chemical byproducts. The incorporators are C. O. and P. H. Patier, and M. J. Farnbaker.

THE EASTERN METAL STAMPING CORP., Newark, N. J., has been incorporated with a capital of \$250,000 to manufacture metal stampings, etc. The incorporators are William G. Viall, Thomas W. Paterson and Frederick A. Slater. The company is represented by Karl Z. Kiefer, 810 Broad St.

THE E. R. NASH LEATHER Co., Boston, Mass., has been incorporated with a capital of \$25,000 to manufacture leather products. Edward P. Nash, Brookline, Mass., is president and treasurer.

THE POCOT OIL Co., Tonawanda, N. Y., has been incorporated with a capital of \$10,000 to manufacture refined oil products. The incorporators are F. G. Demaroe, F. J. Wallenberg and LeR. J. Tiehor. The company is represented by J. A. W. Simpson, Tonawanda.

THE NATIONAL ALLOYS Co., Detroit, Mich., has been incorporated with a capital of \$200,000 to manufacture aluminum, brass, bronze and other metal castings. The incorporators are Horace H. Lane, W. J. Reardon and John G. Collins, 2320 Dime Bank Bldg.

THE MARYLAND VEGETABLE OIL Co., Seventh Ave. and Sixteenth St., Baltimore, Md., has been incorporated with a capital of \$1,000,000 to manufacture vegetable oil products and byproducts. The incorporators are Enos S. Stockbridge, Roland H. Brady and J. A. Knoerr.

THE POSTAL PETROLEUM Co., Los Angeles, Cal., has been incorporated with a capital of \$750,000 to manufacture petroleum products. The incorporators are F. A. Andrew, E. G. Hurst and R. W. Street. Robert M. Fulton, Trust & Savings Bldg., represents the company.

THE SOUTHERN BOTTLE MFG. Co., Tampa, Fla., has been incorporated under state laws to manufacture bottles and other glass products. J. F. Jones, Tampa, is president; A. B. Jones, vice-president and treasurer; and R. L. Rundell, secretary.

THE OXFORD STEEL PRODUCTS Co., Boston, Mass., has been incorporated with a capital of \$300,000 to manufacture steel specialties. Clarence E. Dodge is president; and Maurice T. Viall, 155 Armington St., Cranston, R. I., treasurer.

THE PEABODY LEATHER Co., Camden, N. J., has been incorporated with a capital of \$100,000 to manufacture leather products. The incorporators are Eugene O. Peabody, D. Paul Brown and G. Lewis Mayor. The company is represented by the Corporations Co., 104 Market St.

THE C. F. BATTENFELD OIL Co., Detroit, Mich., has been incorporated with a capital of \$15,000 to manufacture greases, soaps, oil compounds, etc. The incorporators are J. R. Battenfeld, Jack Mourse and L. E. Thomason, Kansas City, Mo.

THE HUDSON GLASS Co., New York, N. Y., has been incorporated with a capital of \$9,000, to manufacture and deal in glass products. The incorporators are F. H. Sparks, R. W. Weed and L. Finkelstein. The company is represented by M. M. Fox, 201 Havemeyer St., Brooklyn, N. Y.

THE BELL CHEMICAL Co., 12 East 58th St., Chicago, Ill., has been incorporated with a capital of \$25,000, to manufacture chemicals and chemical byproducts. The incorporators are Isadore Bell, Henry J. Tenhoope, and Elias Freudenheim.

THE EU-RE-KA SOAP Co., INC., Providence, R. I., has been incorporated with a capital of 480 shares of stock, no par value, to manufacture soaps and kindred products. The incorporators are Benjamin C. Emmons, Thomas M. Webb, and Oscar H. Seavey, 276 Wickenden St.

THE GRANITE DISCOVERY OIL Co., Los Angeles, Cal., has been incorporated with a capital of \$750,000, to manufacture petroleum products. The incorporators are George Dennison, S. J. Bowman, and L. L. Woods. The company is represented by Carnahan & Clark, 756 South Broadway.

THE BEL FAST ADHESIVE Co., Lyndonville, (Orleans Co.), N. Y., has been incorporated with a capital of \$25,000, to manufacture glue, paste and other adhesives. The incorporators are M. P. Barry, G. E. Lyman, and E. E. Belding, Lyndonville. The company is represented by W. S. Garber, attorney, Rochester, N. Y.

THE FAHEY LEATHER STAIN Co., Lynn, Mass., has been incorporated with a capital of \$25,000, to manufacture leather chemical products and affiliated specialties. Daniel J. Fahey is president; and John J. Fahey, 10 Blaisdell Terrace, treasurer.

THE BARRINGTON OIL Co., 1404 Harris Trust Bldg., Chicago, Ill., has been incorporated with a capital of \$1,000,000 to manufacture refined oil products. The incorporators are H. M. Cassidy, E. F. Brubaker, and R. O. Farrell.

THE TERRELL OIL & REFINING Co., Terrell, Tex., has been incorporated with a capital of \$250,000, to manufacture refined oil products. The incorporators are Robert L. Warren and W. P. Allen, Terrell.

THE APEX TIRE & RUBBER Co., Providence, R. I., has been incorporated with a capital of 250 shares of stock, no par value, to manufacture rubber products. The incorporators are John M. Franklin, Charles H. Sprague, and David W. Smith, 104 Franklin St.

THE BITUMINOUS COATINGS CORP., New York, N. Y., has been incorporated with a capital of \$5,000, to manufacture paints, varnishes, etc. The incorporators are W. B. Betzig, R. D. Kenmore and T. O'Callaghan, 115 Broadway.

THE ATLANTIC CARBONIC & CHEMICAL CORP., Chelsea, Mass., has been incorporated with a capital of \$125,000 to manufacture chemicals, chemical byproducts, etc. Phillips Rogers, 195 Winthrop Road, Brookline, Mass., is president and treasurer.

THE GENERAL REPRODUCTION Co., Philadelphia, Pa., has been incorporated with a capital of \$30,000 to manufacture sensitized paper and kindred products. C. R. Ringard, 801 Vernon Road, is treasurer.

THE PETERSON SPRING Co., Detroit, Mich., has been incorporated with a capital of \$20,000 to manufacture steel springs, wire goods, etc. August Peterson, 4762 Townsend Avenue, is president.

THE CO-OPERATIVE OIL CORP., Long Beach, Cal., has been incorporated with a capital of \$350,000 to manufacture petroleum products. The incorporators are J. D. Hawk, J. S. Bradley and L. J. Keck, Long Beach. The company is represented by L. H. Wealton, 206 Marine Bank Bldg., Long Beach.

THE STERLING EXTRACT Co., INC., Wilkes-Barre, Pa., has been incorporated with a capital of \$10,000 to manufacture extracts, chemical compounds, etc. David Walkman, Wilkes-Barre, is treasurer.

THE MONROE OIL & REFINING Co., Fort Worth, Tex., has been incorporated with a capital of \$1,000,000 to manufacture refined oil products. The incorporators are V. S. Monroe, Fort Worth; and R. W. Perry, Polytechnic, Tex.

THE OHIO-KENTUCKY FLUORSAPAR & LEAD CORP., White Castle, La., has been incorporated under Delaware laws with capital of \$1,000,000 to operate production plants for fluorspar, lead and kindred products. The incorporators are Thomas J. Clay, White Castle; C. P. Shaver, Thibodeaux, La.; and F. B. Moody, Smithland, Ky. The company is represented by the Colonial Charter Co., Ford Bldg., Wilmington, Del.

New Publications

BOOKS

A DICTIONARY OF APPLIED CHEMISTRY. Vol. I, revised and enlarged edition. By Sir Edward Thorpe, assisted by eminent contributors. Pp. 752, illustrated. London and New York: Longmans, Green & Co., 1921. Price, \$20.

Volumes of this revised and enlarged edition of Thorpe's Dictionary will be issued at intervals during the next two years. Volume I is now ready and Volume II will probably appear during this summer.

An approximate idea of the amount of new material added can be gained from the fact that the new Volume I devotes 752 pages to subjects from Aal through Calcium, whereas this same range was covered in 614 pages in the previous edition. Six volumes will certainly be needed to complete the work and it is possible that a seventh will be required.

The work of revision has been carefully and thoroughly done and new articles have been prepared to cover recent developments, so that this work will maintain its position as the greatest contribution in English to the literature of applied chemistry.

TABLES OF REFRACTIVE INDICES, VOL. II—OILS, FATS AND WAXES. Compiled by R. Kanthack. Edited by J. N. Goldsmith, Ph.D., M.Sc., F.D.C. Pp. 295. London: Adam Hilger, Ltd., 1921. Price, £1, 5s.

This critical compilation of refractive indices of oils, fats and waxes is Volume II of a series from the research department of Adam Hilger, Ltd., Volume I on the refractive indices of essential oils having been published in 1918.

The present volume contains over 2,500 measurements on over 500 oils, fats and waxes, together with references to the original sources of information, so that it should prove invaluable to workers in this field.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold its twenty-first annual meeting at St. Louis, Feb. 27 to March 2, 1922.

AMERICAN CHEMICAL SOCIETY, THE SOCIETY OF CHEMICAL INDUSTRY and the American Section of the latter society will hold a joint meeting in New York, Sept. 6 to 10.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in Lake Placid, N. Y., Sept. 29 and 30, and Oct. 1.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its fall meeting at Wilkes-Barre, Pa., Sept. 12 to 17.

AMERICAN MINING CONGRESS AND NATIONAL EXPOSITION OF MINES AND MINING EQUIPMENT will hold its twenty-fourth annual convention in the Coliseum, Chicago, Oct. 17 to 22.

AMERICAN SOCIETY FOR STEEL TREATING will hold its third annual convention and exhibition Sept. 19 to 24 at Indianapolis.

THE NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SEVENTH) will be held during the week of Sept. 12 in the Eighth Coast Artillery armory, New York City.

NEW JERSEY CHEMICAL SOCIETY has discontinued meetings for the summer and will resume them in October.

SOCIETY OF CHEMICAL INDUSTRY (BRITISH) at the invitation of the Montreal section will hold its annual meeting in Montreal and other Canadian cities during the week of Aug. 29, 1921. Details will be printed in this magazine from time to time.

SOCIETY OF INDUSTRIAL ENGINEERS will hold its fall meeting at Springfield, Mass., Oct. 5 to 7.

TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its fall convention with the American Pulp and Paper Mill Superintendents' Association, at Washington, Philadelphia, Spring Grove, York, York Haven, Pa., and Wilmington, Del., Oct. 18 to 20.

Number 6

Fair Dealing With Washington

IMPORTANT negotiations are now under way in Washington and much depends upon the forthcoming legislation. The chemical industry occupies a prominent position in these considerations, and Congress is naturally relying on the representatives of that industry for assistance in solving many of its problems. The industry in turn is relying on its representatives to present its case fairly and frankly, and it is therefore deeply concerned with the recent reports that this has not always been the case.

The hearings before the Congressional committee in charge of tariff legislation are occasions where willing co-operation and patient service are sorely needed. The committee is in search of certain definite information, and oddly enough it is not satisfied with broad generalities and sweeping statements of impending floods of cheaply made foreign goods. In attempting to fix a tariff rate in terms of production costs and foreign market values, the legislator must have specific facts and figures. The Senator who in recent hearings demanded data on costs, profits and dividends was well within his rights, although it must be realized, of course, that information of a confidential nature cannot always be given in the public hearings. There are ways and means, however, by which such data can be presented to Congressional committees, and our chemical manufacturers must at least show their complete willingness to meet these requirements.

The efforts of the Department of Commerce to be of real assistance to industry are also in certain instances being met in a half-hearted way, and here again the chemical industry is among the offenders. Many industrialists are betraying a manifestly selfish attitude toward this worthy enterprise. Apparently there is the fear that more information must be given than will be received, and that therefore the Government's activities are to be regarded with suspicion. Even the well-considered program for a useful statistical service is not receiving the genuine and frank support it deserves from our industries. Secretary HOOVER'S broad plans for a comprehensive study of the facts and figures for all business demanded relatively little of the chemical manufacturer. Only a half-dozen important chemicals were on the list for production statistics, but still there are some of our producers who are objecting because they fear that the Government is encroaching on their business and they resent "government in business."

In many cases these same manufacturers are the ones who are seeking special favors from Congress. The very controversial measure of protection demanded by the dye industry, badly needed as it is, is still regarded in many localities as a special dispen-

sation for a particular industrial group. The approaching expiration of the import control on dyes and organic chemicals also creates a serious emergency, and a special effort must be made to bridge the gap between August 27 and the final enactment of the permanent tariff. In the face of these special demands for vitally important legislation, can we afford to withhold any information from Congress? Obviously, we cannot. If mistakes have been made in the past, it is time they be rectified, for the chemical industry must adopt a frank and open policy in its dealings with the Government.

Alcohol Dyes and Industrial Supremacy

A COMMITTEE was appointed recently by the British Government to report on the dye industry, and its findings are being published serially in the *Chemical Age* of London. The industry began in Manchester in 1856 with PERKIN'S discovery of mauve. That much seems settled. Its decline and fall in England coincident with its rise and prosperity in Germany is a phenomenon for which the committee has tried to discover the reason. And after long research it gives as one of the two leading causes "the lack of duty-free industrial alcohol throughout a long and critical period during which the Germans, having the advantage of duty-free alcohol, were able to produce dyes at a correspondingly lower cost than British manufacturers."

Other attributed causes we shall consider later. We have already noted this finding, but it will do us no harm to ponder over the alcohol problem again. We can produce alcohol as cheaply as the Germans, and probably more cheaply than they, because we have the facilities, the technique and more abundant materials. The dye industry is also here. It needs the alcohol to make dyes, but not to drink. The Congressional mind, however, as exemplified in Mr. VOLSTEAD and his followers seems to hold that if alcohol goes into the apparatus in which dyes or the materials to make dyes are made, it must also come out with the product; that the product must be "booze," because the makers put alcohol into it.

It may seem easy to disprove such a postulate, and indeed it would be were it not for the fact that there's none so blind as he who will not see. The trouble is that in this country the problem of industrial alcohol has entered politics, and politics in its modern sense has almost ceased to be a host to reason or logic, or even the consideration of anything else than scare-heads. Its principal business is to swing the crowd before it can think, and when a crowd is once well swung, it does precious little thinking. This is not a pleasant thought, but unfortunately it is true.

For instance, last fall in Minnesota there was wit-

nessed the amazing phenomenon of the defeat of state-owned grain elevators on an issue of free love. We have no interest in either proposal; we give it merely as an illustration of swinging the crowd. The farmers either rightly or wrongly wanted state-owned grain elevators. An enthusiastic supporter of the somewhat radical idea recommended that voters read a number of radical books and in the list was included a work by ELLEN KEY. In one of her works were found some caustic criticisms of present conventions relating to the institution of marriage. This was construed to favor its total abolition, whereupon the opinion that free love and not elevators was the real issue was framed up and published broadcast by the ladies whose husbands were interested in privately-owned elevators. The farmers, including thousands of seasoned old Swedes and Norwegians with large families and all the traditional Scandinavian piety, protested in vain that they didn't want free love, that they wanted elevators and proposed to cling to their good wives—but the scarehead was well framed up, the crowd had been started at shouting and the protest against free love carried the day.

Now we have the dye, pharmaceutical, varnish and general chemical industries all mixed up in Congress, not with prohibition but with what THEODORE ROOSEVELT called "the lunatic fringe" of prohibition. Truly we are in a parlous state in regard to industrial alcohol.

Soft-Pedaling the Curtailement of Research

OF RECENT years it has been fashionable to make widespread public announcement of the research facilities maintained by manufacturing establishments. The public has been taught and can well believe that a company maintaining such agencies for investigation and development is apt to have the latest and the best product, continually improving it to utilize every advance in the art.

However, a new phase in research activities has been noticed with great regret during the times of depression which have come like an industrial blight upon the country during the past year. In this period many of the research and development laboratories of big corporations have been discontinued and still more frequently these departments have been reduced to a bare skeleton of their former glory. It is noticeable that when this has been done the corporations have been very modest in their announcement of the change or have altogether suppressed the news where suppression was possible. In this there is both encouragement and warning.

The encouragement comes from the fact that industry apparently recognizes that cutting off research and development work is really poor policy. It recognizes that it would be much better to continue these departments, for they are essential to efficiency and at no time is efficiency more important than in time of stringency. The fact that little mention is made of discontinuance of laboratories shows that the management of corporations knows that the public will look with suspicion upon tendencies in this direction. And the public may well ask whether the interruption of research does not mean that the corporation will no longer progress and that its product may fall behind in the race under the keen competitive conditions of the coming few years. The signs are so plain that "he who runs may read."

Simultaneous

Discoveries in Science

PHILOSOPHERS have argued that discoveries are made when the world is ready for them; that a man arises when he is needed, and his name is a matter of no moment. If, they say, CROMWELL had not been at Naseby, some other Puritan would have been Lord Protector. NEWTON was but an incident, apples were falling everywhere and gravitation could not long have remained undiscovered. The studies of any one of a dozen scientists would ultimately have led him to the discovery of radium, but the CURIES happened to arrive there first.

About the only foundation for this theory is the undoubted historical fact that many of our most important truths were discovered independently and practically simultaneously. In not a few cases important conclusions were reached years before the world was ready for them, and then lay forgotten, only to be rediscovered when the time was ripe. Who can count the many controversies as to priority, both in and out of the patent courts? LIPPERSHEY in Holland and GALLILEO in Italy both discovered the telescope. KELLY in America and BESSEMER in England both invented the pneumatic process of making steel. The same day that NICHOLSON announced the presence of a new gas in the great nebula of Orion, a German, WOLFF, read a paper in Heidelberg in which he showed that two of the spectral lines which NICHOLSON could not explain were due to the fact that the nebula consisted of two parts.

The recent paper by JEFFRIES and ARCHER, published in these columns, on "The Slip Interference Theory of the Hardening of Metals," furnishes more striking evidences of simultaneous arrival at the same point by two widely separated investigators. At about the time their manuscript was completed another was read before the British Iron and Steel Institute by the Swedish investigator Dr. ARNE WESTGREN. Both papers contained the new experimental result, proved by X-ray analysis, that ferrite and martensite both contain body-centered cubic crystals of iron, whereas austenite contains iron atoms in face-centered crystals. The peculiar thing is not that austenite is austenite whether in Cleveland or in Gothenburg, but that its crystallographic nature should have been announced in two papers at the same time. A further fact, more than a coincidence, is this: An issue of the *Proceedings* of the Royal Society was on the way from England containing a paper (reprinted in this issue) by Dr. ROSENHAIN of the National Physical Laboratory setting forth views on the hardness of solid solutions substantially identical with those proposed by JEFFRIES and ARCHER.

A rather striking parallel can be drawn. JEFFRIES and ARCHER in their paper which was mentioned above say:

The resistance to permanent deformation, which is a general measure of hardness and strength, represents resistance to the beginning and propagation of slip Our knowledge of the structure of solid solutions is quite limited, but from the results so far obtained it seems that the atoms of the solute replace those of the solvent without substantial change in the space lattice of the latter. . . . The increased hardness and strength are traceable directly to increased interatomic forces, the attraction between unlike atoms being in general greater than between like atoms. We may conceive an additional mechanical factor in the form of a roughening of the slip planes due to the

presence of atoms of unlike size, or, as Bridgman puts it, a staggered arrangement of the atoms.

We now quote ROSENHAIN:

The forces acting on any atom of A, for instance, when one of its neighbors in the lattice is an atom of B, cannot possibly be the same as those acting on an atom of A entirely surrounded by atoms of A; there must be some want of symmetry in the forces acting on an atom so placed, with a result which is perhaps best expressed by saying that such an atom will be pulled slightly out of its proper place. . . . It is evident that such distortion must affect the internal energy of the whole system. Anything which tends to hinder the free occurrence of slip on the principal planes of a crystal will increase the hardness. . . . Any, even slight, distortion of the space-lattice of the crystals of a metal by the presence of "dissolved" atoms of another metal . . . must serve as a hindrance to slip on the crystal planes. Strictly speaking, in fact, the crystal "planes" have ceased to exist in such a slightly-distorted crystal. . . .

Quality Pays

In the Long Run

NO OTHER factor can be as potent in causing disaster for an industry as the failure of its customers to continue to buy the industry's product. At the present time the zinc producers find this as one of the factors in their industrial distress. If they were simply suffering from inability of their purchasers to use their product because of reduced scale of operations there would be no point in discussing their situation. But there is another factor in this case which makes the matter of particular significance.

Dr. H. FOSTER BAIN, director of the Bureau of Mines, in a discussion of this industry states: "The increasing use of black sheets (instead of galvanized) can be blamed in part on the increasing tendency, particularly during the war, of certain manufacturers of galvanized wire and galvanized sheets to use too thin a coating of zinc." In Dr. BAIN'S opinion this has resulted in a loss of confidence in galvanized materials especially among the smaller users who have not had facilities for judging just why it is that they have suffered losses through failure of galvanized materials.

Undoubtedly most of the larger producers of galvanized materials did not follow any such short-sighted policy as to willingly furnish inferior products even when zinc was high or hard to get. It is the shyster of the industry who always indulges in such practices. And yet not only the shyster but also the reputable operator suffers.

In metal products as in every other line of business, honest quality in the long run is the most satisfactory product from the manufacturers' point of view as well as from the standpoint of the user. No industry can afford to permit any member of the business to have his product unnecessarily fall into disrepute as to quality. More than high-grade technology is needed. Broad co-operation in maintenance of industrial standards is also essential. At times it may seem that this co-operation gives the smaller producer an unfair advantage compared with the larger concern with which it is in competition and yet in the long run it is often found that the large operator gains fully as much as the small by this mutual support in the application of the best technology and maintenance of appropriate industrial standards. The next time a case of inferior quality among smaller producers arises, let everyone involved think of the present situation among the zinc producers.

An Era of

Construction in Prospect

THAT the people of the United States are going to be busy as soon as they can get on the right basis for being busy may be accepted practically as a foregone conclusion. The real question is what they will be busy about. Some have argued that we have such a large productive capacity that we can do much more than supply our own needs, and must have a large export trade. That raises the question what we should get for our exports. If we have a surplus of goods we scarcely want to be paid in goods, for the goods we cannot produce and still can use would hardly measure up well in quantity or value against the goods we could export. We do not want gold. If we accepted securities, we should probably be getting part ownership in construction works outside the country. Why not have construction work in this country?

That we can take care of our current requirements without working hard was shown by the experience of 1920. Men did not work hard then by any means, yet in many lines surpluses were created.

In construction work there is an unlimited field for our surplus energy, and it is obviously in that direction that the energy should be directed. We need more dwelling houses if we wish to be comfortable and if we can get them at the right price, while if the price is low enough we ought to abandon a great many of the dwelling houses we have.

The distribution of power presents an excellent field. Our system of power and heat generation has grown top-heavy. The last two doublings in coal production were less than fifteen years apart and the preceding doubling had required only ten years. From 1880 to 1918, thirty-eight years, instead of the production of coal doubling three times the production was multiplied by 9.5. Nothing like such a pace can be continued, as the old-fashioned methods of production and shipment cannot be improved sufficiently in detail. The solution is to adopt new methods entirely, converting coal at the pit mouth into high-tension current and making byproduct coke for such fuel as must be provided. It is easier and better to construct along that line than to construct more railroads. There is nothing the matter with byproduct coking except possibly the high level of construction cost as it has been lately. Of the coke produced in the United States last June about 86 per cent was byproduct and 14 per cent beehive, although as to capacity there is not far from a 50-50 division. That is only a beginning, however. The proportion of all coke that is byproduct may be fairly high, but the proportion of all coal mined that is coked at all is very low. Where there is water power it is of course far more economical to develop it than to mine coal.

In construction work there is no limit. Of food and clothing we can conveniently use only so much. With construction work the field is unlimited, the only problem being to make it pay. And in order to make it pay the cost must be sufficiently low. A great deal of progress in that direction has been made in the past few months. The condition is the same as that of a commodity market when there is a latent demand, but the commodity is not low enough priced. It is compelled to make its market by developing a suitable price.

Oxygen Research of the Institut de Beauté

To the Editor of Chemical & Metallurgical Engineering

SIR:—A colleague with a high thoughtful brow sent me lately a circular of the Institut de Beauté de Paris which contains so much new chemistry that I venture to add a few excerpts from it to my former contributions on the unfamiliar aspects of science. The Institute, according to its circular, addresses itself to the culture of the human hair and its growth. It does not appear to extend its activities to include harvesting, or barberology.

The thesis is presented that "there is no such thing as a dead hair root" and it is claimed that no matter how bald we may be, the "roots" are all there, in the scalp, but in an atrophied condition. The proof offered in support is that if the roots were to die, Nature would expel them like so many splinters and that we should therefore have dreadful eruptions of the pate during the process of growing bald; and the irritation, according to the circular, would be beyond endurance. The same authority declares that "the roots of the hair and the roots of the grains and grasses of the field need one and the same nourishment" and that this is oxygen. "Introduce oxygen into the roots of the hair," it continues, "and . . . the most shiny bald pate responds to the nourishment just as a plant does to the air." "What would happen to a plant," is asked in the circular, "if you put it in a dark place and excluded all the oxygen from it?" From this we gather our first note that there isn't any oxygen in the dark.

In the preparation of an "oxygen product" to induce the atrophied roots of the hair to "breathe" and thus to grow, "we have done," affirms the publication of the Institute, "what science insists is absolutely impossible. *We have liquefied oxygen.*"

It may seem that this has been done before; indeed I recall your frequent references to the Linde, Claude and Norton processes, but it would appear from the revelations of the Institute that its savants have developed a remarkable allotropy of oxygen. For instance, if liquid oxygen, as prepared under the Linde, Claude or other patents, were applied to a bald spot, it might well cause the remaining hair to curl, but it would hardly make new hair to grow over the vacant spots. Dr. Metzger of the Air Reduction Company refuses absolutely to recommend applications to the scalp of liquid oxygen prepared by the Claude process for any purpose whatever, and even in the hottest weather, Dr. Metzger is very firm in this advice.

As evidence of the originality of the contribution of the Institute the circular declares that "Just what a step in scientific research this achievement is, only the medical profession can appreciate." This statement is, in itself, a credential of the Institute, because while I do not profess to know the mind of the medical profession I think I am in a position to say that the chemical profession does not appreciate it. We must remember, however, that there is a great deal of original chemistry in medicine. An eminent practitioner told

me once that the object sought in the aging of wines or liquors is "to get rid of all the ethyl bodies."

Another point brought out in the circular of the Institute which chemists do not understand is this: "The oxygen is an ether that evaporates as soon as the air touches it." It "disappears as soon as the vial is opened." But "by a long and tedious process in electricity" the members of the Institute have "imprisoned oxygen" and this is their "very own invention." "We have succeeded," they claim, "in capturing the ozone needed for the health of the hair roots and in bottling it in a fashion that will preserve the strongest quality of oxygen indefinitely." Then "even though the bottle be uncorked, the oxygen will not evaporate from this air-giving lotion, and only when it is rubbed into the scalp and the temperature of the body sets free the imprisoned oxygen can this genuine ozone be absorbed into the deep-down roots of the hair." After this is accomplished it is affirmed that "the hair will curl and wave naturally and vibrate with your own human magnetism."

Revelations come so fast in the foregoing that we can hardly catch them as they fly. But besides the note that oxygen will not keep in the dark we learn that oxygen is an ether.

The hunt for and capture of ozone is still a secret process, but I suggest that probably the Institute has its own preserves and shoots ozone with electric guns. Ozone is absorbed by the "deep-down" roots of the hair. This leads to a quest for a proper name for this product with new qualities.

How would "Osmotic Ozone" do? Or "Cute-oze" (cute from "cutaneous," not from "nifty")?

The synchronous vibration of hair of the scalp with human magnetism is also new. I once knew an old deacon whose tuft of chin whiskers used to vibrate with his own human magnetism after the absorption of one or two milk punches into the face above the beard, but this was not a scalp phenomenon. The Institute is entitled to all credit for the scalp shakes.

MARTIN SEYT.

Inventors Are Active

Despite the industrial depression, applications for patents during the first six months of 1921 broke all records. Applications for patents during that period numbered 45,005. This is nearly 300 more applications than the best previous half-year period. Although the demands on the Patent Office are increasing, its capacity is limited to the volume of business of twenty years ago. There is pending in Congress a bill providing for some additions to the force and for some increases in salaries. This bill probably will pass in the near future, but even it will not meet the exigencies of the situation. It seems probable that applications will continue to accumulate until the pressure becomes sufficiently great to induce legislative relief. The failure to provide adequate machinery to handle promptly all applications for patents is particularly difficult to understand, since the office is more than self-sustaining.

American Ceramic Society Summer Meeting

Announcement of Appointment and Scope of Activity of Full-Time Secretary for the Society—Important Effect of This Step on Development of Research and Industrial Advancement in the Clay-Working Business—Social Features and Plant Trips

PERHAPS the most successful summer meeting of the American Ceramic Society was convened in the pottery district of southeastern Ohio, with headquarters at the Hotel Courtland, Canton, Ohio, lasting for three days, July 25-27. These meetings are usually called for the sole purpose of visiting industrial plants in each particular district, with social features to bring closer personal relations between members. On this occasion the program was carried out by the local committee under the direction of Ira E. Sproat with such excellent results as to win the approbation of every member attending.

At the banquet Monday evening President Pence announced the action of the board of trustees in retaining the services of Ross C. Purdy to act as full-time secretary. In response to the requirements of the times and expressed desire of the society, the board has employed Mr. Purdy to serve the remainder of 1921 as organizing and next year as general secretary. The object of this action is none other than the object for which the society was founded, and for which it has for twenty-two years been maintained—"to advance the ceramic arts and sciences."

Mr. Purdy was called upon to give further details and responded in part as follows:

Abstracts of Mr. Purdy's Address

The organizing work of this secretary can be generalized in the words of the special committee in its report to the board of trustees, which report was accepted and approved, and the section under the caption "Duties of the Proposed Permanent Secretary" was made a part of the contract of employment.

The scope of the organizing secretary's authority is limited to "assisting," "supplementing," "supporting" and "aiding." He is to encourage, promote and execute only by the authority of, in the name of, and through the board, the committees, the local sections or the divisions, as each case will require. In other words, he is merely to assist, support, aid and supplement the existing agencies already provided for by the constitution and bylaws.

By the appointment of an organizing secretary to serve in the capacity of an assisting and supporting supervisor of the work of the committees, sections and divisions, the board of trustees for the first time has a means of co-ordinating and unifying the work of the entire organization on the one general program of advancing ceramic arts and sciences. Emphasis should be placed on the fact that the organizing secretary cannot and will not relieve the committeemen nor the officers of the local sections and divisions of their responsibilities.

Research financing by associated corporations is the vogue today, whereas in former years the industries supported general ceramic research without regard to special applications. As the industries progressed in

things technical, they learned the value of joining by groups in financial support of researches in which they were particularly interested. Thus their support of and interest in scientific and technical research gradually shifted from the general to specialized investigations. The advantages of group specialization, emphasized as they were by war conditions, was recognized by the American Ceramic Society by providing industrial divisions. These divisions have succeeded or failed according to the quality and the continuity of executive attention given by the division officers and also according to the extent to which they have enlisted their particular group of manufacturers in the support of scientific and technical research. It is to correct these shortcomings that the organizing secretary was appointed, for the success or failure of the division is the success or failure of the society as a whole in serving the different groups of ceramic industries.

The American Ceramic Society has been and will continue to be the principal agency for the advancement of ceramic arts and sciences. In the early days, when there was but one collegiate department of ceramics, no federal bureaus, and when the manufacturers were jealous of their trade secrets, Prof. Edward Orton, Jr., did a great service to the ceramic industries when he persuaded a few ceramic workers to join in the founding of the American Ceramic Society. Since 1899 this society has continued steadfast to its original purpose, and was and is deserving and is enjoying the support of the ceramic industries, with the result that today our industries are second to none and equal to any in the world in technical attainments.

It is intended that this society shall continue as the leading agent for the advancement of ceramic technology, and it is assured that each division will enjoy in this purpose the full co-operation and backing of its respective group of manufacturers with the same zeal and for the same purposes with which, in previous years, the society as a whole was supported.

That all this may be realized and thus carry to full fruition the purposes and hopes of Prof. Orton and his collaborators, the board of trustees has appointed a full-time secretary and given emphasis to the organizing duties as distinct from the routine, and it is to the carrying through of this program that I, the appointed secretary, pledge my ability, zeal and singleness of purpose, and it is to this that the full co-operation of each and every member of the society is asked.

The Board of Trustees' Meeting

Tuesday night the board of trustees met for dinner and a business meeting. The more important business taken up concerned the activities of the new organizing secretary. Part of his program as submitted to the board was read before the members at the Elks Club luncheon in East Liverpool, Ohio, Wednesday noon. Abstracts follow.

A general program, to which all can work, is essential to definiteness in policy, cohesiveness in organization and maximum success; the prime requisites to obtaining the largest returns in things accomplished with the expenditure of the least time and money. To this end there are two suggestions, (1) that a conference be called of members of the board, officers of divisions and local sections and chairmen of standing committees, and (2) that a program be prepared for such a conference, which program can be issued and freely discussed prior to the conference.

One of the fundamental requisites to the most perfect attainment in the organized activities of a society like ours is close contact with the individual members of the society by finding some way for each to be actively

where for the very service for which our society is maintained have not known that we would thus serve them, and (3) some of our standing committees have not known what or how to do and where to obtain information. Neither the board nor the *Journal* has met the situation just described and could not have done so in any other than some way as is here proposed.

DIVISIONS

The plan of organization and general purpose of the divisions are defined in the constitution and bylaws, but the constitution very properly leaves to the decision of the division members the manner in which these purposes shall be served. Although a detailed arbitrary plan or program cannot be made alike for all divisions, there are some things that could be practiced in common by all: The divisions should have semi-annual or quarterly meetings for consideration of research problems and plant visitations. One or more of these meetings, when possible, should be held in conjunction with meetings of trade associations.

Each division could plan these mid-year meetings in part as institute meetings for the benefit of superintendents, foremen, etc.

Opportunity could be solicited for reciprocal participation in progress and contributions to literature with associations of users of the ceramic materials.

There should be a close affiliation of the standards committee of each division with the committees in the American Society for Testing Materials having like interest, such affiliation being by one or more members of the divisional committee having membership on the A.S.T.M. committee. A way for our society having official representation as a society on all A.S.T.M. committees dealing with ceramic products is now being devised.

Each division should have a definite program of research with assignments to federal, school and industrial laboratories, involving, when feasible, plant-scale trials. There need be no curtailment of reports of private and individual researches, but co-operatively planned and executed researches among the division members would make much for teamwork.

Co-operative research finances by persons or organizations outside of the division should have such supervision by the secretary as shall be decided by the board of trustees in general and the division in detail, but understanding should be had with the laboratories and all other parties concerned that the results must appear first in the bulletins of the society or the supporting associations rather than as announcements by the laboratories to trade journals.

Reports of plans for co-operative researches and progress reports should be made to the society as a whole as news propaganda that creates appreciation for the society. This would in no way hinder or detract, but would render a service beyond and aside from the actual result obtained.

A definite schedule of meetings of the divisions should be agreed upon so as to prevent conflicts of dates and also to permit of time and place distribution as would best promote the society as a whole without loss to the purposes had by any of the divisions.

LOCAL SECTIONS

With the exception of the New Jersey Section, which has had a definite goal, the local sections have been without definiteness in purpose and program of pro-

ROSS C. PURDY

engaged in or constantly informed of what is being done or planning to be done in the section and division to which he belongs, and to be kept informed of the plans and doings of the committees. Such may be thought accomplished as far as it can be by the reports now appearing in the *Journal*, but this is not quite correct, for those reports are lacking in the personal appeal to co-operate in the planning and execution of the work. This means, in the last analysis, that there is a need of and a virtue in an inter-member and inter-group of members correspondence that will instill a desire to serve, a feeling of welcome for his service and opinions, and a co-operative obligation and interest.

It is no mere phrasing of general thoughts or theories, but a bald statement of facts, that, because our society has been without a definite and known general program on which each and all groups within the organization could be working, (1) our members are not as well satisfied as they should be, (2) the associations which would naturally look to us rather than else-

cedure, which lack has resulted in much misspent and early spent enthusiasm. They have found no way of interesting the local manufacturers in the society through the local section.

It is true that the problem of each section is different in many respects, but unless these sections are prompted to do for their district that which the activities of the society as a whole will prompt the manufacturers to want, other agencies will usurp our "rights and benefits."

To be definite with a concrete example, the local sections covering Zanesville and East Liverpool could with profit to all concerned organize institutes in these cities, holding classes, operating a laboratory and providing for lectures, etc. The local manufacturers would support such institutes and it would be of advantage to them that the institute was being managed jointly with them, they carrying the financial responsibility and our society through the local sections the instructional responsibilities. Unless our society promotes such enterprises in different sections, the local interests will do this and the society thus lose opportunities.

Local sections should have regularly scheduled meetings and much attention should be given that the programs are attractive.

Co-operation in joint meetings with local sections of other societies should be encouraged, but in these the American Ceramic Society section should do its share.

The local sections should make a list of the ceramic concerns and important users of ceramic products in their district and assist in compilation of data whenever any agency within the society should issue a questionnaire.

There is a need of redistricting of local sections and a need of keeping the section officers notified of members leaving or moving into their districts.

CHANGE IN CHARACTER OF JOURNAL

In the past the *Journal* has been the society's main point of contact between the members and will continue to be such until the local sections, divisions and committees begin to function under the stimulus of the board through the secretary. The *Journal*, however, has not served as successfully in this respect as it would if changed to include "industrial journal" features.

We have lost considerable of the personal or human element in our publications through loss of the discussions, but even a trade journal with the discussion added to the technical papers would not actuate the members to research, either individually or in groups, as would more direct stimulating methods. In every organization it seems to be necessary to have frequent personal contact and a subject of common interest other than the *Journal*.

It is wise for the society to consider adding the news feature and shop discussions to the two divisions the *Journal* now has and in addition to this make more use of bulletins than we have in the past.

ACTIVITIES OF THE STANDING COMMITTEE

In the correspondence relative to full-time secretary, there were suggestions of how the committee on research could co-ordinate its work with the work of the divisions. There are overlapping interests in this instance which cannot be removed and which, if properly directed, would really be of benefit. Similarly, there

are overlapping interests and duties among the different committees.

The programming of the activities of the committees would depend largely on the general program adopted for and by the local sections and divisions; hence the importance of the conference.

CENTRALIZATION OF BUSINESS AND ACTIVITIES

This is a question for decision by the board, but there are interests involved aside from those of the board. It is true that the selection of an editor and determination of official relations between the general secretary and editor are to be made by the publication committee and the board. It would seem to be worth while, however, for such a conference of executives as is here proposed to discuss this and perhaps formulate recommendations.

AFFILIATION WITH THE NATIONAL ASSOCIATION

We accepted affiliation with the National Research Council without members of our board (and apparently the appointees on the Research Council committee) knowing just what the affiliation meant in obligation, liability or benefit to either party. For four years we have kept ourselves blind to the possibilities and limitations in our affiliation with the National Research Council, with the result that our committees have served the council wholly, our society being concerned and credited only in a very incidental way.

It is a duty to ourselves in particular and to the ceramic fraternity in general that the Research Council committee inform us on this question of our affiliation with the Research Council.

There are three items in this connection worthy of discussion in this suggested conference: (1) Should not the personnel of the Research Council be representative of the different divisions and of both the laboratory and the plant, and (2) should our society join the Engineering Division of the council as well as that of the Division of Chemistry, and (3) should ceramists be styled as a group of ceramic chemists, whereas a large part of ceramic work is engineering and the largest part of graduates of ceramic courses are called engineers?

The American Society for Testing Materials offers an opportunity for our society to co-operate officially with manufacturers and users of ceramic products in the work of standards and methods of testing, etc., that would bring into prominence before the technical and scientific world the service that we are rendering. This is important, and as it would touch upon the particular interest of each group in our organization, it should be thoroughly investigated and presented to the suggested conference.

SOURCES OF REVENUE

Final decisions on finances are left with the board, but to know in what way our resources can be increased requires acquaintance with the men of affairs in the several industries which only representatives from that group can have. Then, too, there are related interests which would ally with us in the support and prosecution of co-operative researches. The possibilities and extent of such alliance are properly a subject for general discussion.

There are other topics which properly would come before such a conference for discussion and recom-

mendations, but it is thought that the foregoing suggestions are sufficient to be a basis for decision as to whether such a conference should be called.

Plant Visits and Social Features

On the morning of Monday, July 25, visits were made to the Dueber Watch Case Co. and the Hamden Watch Co., in Canton, Ohio. Among details of production were the recovery of waste gold products to be used in plating cases involving pulverizers, briquet machines, blast furnaces, melting reverberatories with sliding hearths and electroplating apparatus; heat-treating processes for the watch case parts and plant for enameling watch dials.

In the afternoon a trip to the Bonnot Co. enlightened the visitors on methods for the manufacture of modern clay-working machinery. The Canton Stamping & Enameling Co. plant occupied a considerable part of the afternoon. This company produces a mottled gray kitchenware by burning the enamel in one firing. The steel is shaped to proper dimensions in a machine shop equipped with large stamping tools, electric spot welding outfits for attaching handles and annealing ovens. The next step involves pickling in large vats in sulphuric acid solution. From the pickling room the ware is transported in small industrial cars to the dipping hoods and washed in slightly acid solution. To this

wash solution is added a small quantity of sulphate salts. After the ware is hand-dipped in the enamel slip it is placed on rack cars to dry slowly. During drying the rust spots from the sulphate solution appear in irregular formation throughout the white enamel. When the ware is burned these spots fire to a dark gray, giving a mottling of dark and light gray spots over the surface of the finished piece.

Delightful banquet and evening entertainment were provided at the Congress Lake Country Club. This was the outstanding social event of the meeting and was well concluded by informal dancing.

On Tuesday the Richardson compartment kiln equipment at the Alliance Brick Co. held the interest of the visitors all morning. After a pleasant luncheon at the Alliance Country Club the party was carried by automobiles to the Sebring potteries and the Strong Enamel Co. at Sebring, Ohio. Returning to Canton in the evening, some of the members attended an informal smoker, while others with their ladies danced till a late hour at Myers Lake.

Wednesday was spent at East Liverpool plants. Luncheon was at the Elks Club, where refreshment and food added zest to speeches and applause alike.

Later issues of CHEMICAL & METALLURGICAL ENGINEERING will describe the Ohio ceramic plants in detail.

Low-Temperature Carbonization*

BY SIR GEORGE BEILBY

I HAVE for many years taken a deep interest in the production of a solid smokeless fuel for domestic purposes by the carbonization of selected coals at 550 deg. to 600 deg. C. The resulting coke is entirely free from smoke-producing hydro-carbons, while still containing 10 to 12 per cent of volatile combustible matter, which burns with a very slightly luminous, perfectly smokeless flame. When the coke is kindled, it becomes enveloped by these flames, which quickly raise the surface to incandescence. Undoubtedly, if this smokeless solid fuel could be produced at a cost permitting of its being sold at little more than the price of the coal which it would replace, it would lead to a complete revolution in domestic heating, and, among other good things, to the abolition of black smoke from house fires. This attractive prospect has been spread before our eyes for many years by enthusiastic inventors and company promoters, yet its realization seems always to move a little further into the future!

From the experience of the past two years at the Fuel Research Station with a considerable variety of coals, we know with certainty the yields and quality of the gas, oils and coke produced under definite conditions, but this knowledge is only the first step in the inquiry. For, until we know with equal certainty the cost of producing these, and the markets in which they are to be disposed of, no economic balance sheet of any real value can be arrived at.

Let me illustrate the market uncertainty by a few comparative figures. Assume that 15 gallons of fuel oil suitable for naval use can be obtained from a ton of coal. Six months ago the value of this oil could safely be taken at 1s. per gallon, and the 15 gallons

would have realized 15s. Today the price of this oil is only 4d. per gallon, and the product would therefore only realize 5s.—a drop of 10s. per ton on the coal carbonized. It is obvious that a method of carbonizing which would have paid its way handsomely six months ago would today result in a loss. My own belief is that low-temperature carbonization can only be established on a sound commercial basis with low operating-costs and a very moderate margin of profit.

Prior to 1914 the shale oil industry in Scotland was distilling 3,000,000 tons of shale per annum. The entire cost of the carbonizing operation, for labor, maintenance and fuel, was 1s. 6d. (36.5c.) per ton, and the margin of profit on which fair dividends were paid was 2s. 6d. (61c.) per ton. Unless the costs and profit margins of low-temperature carbonization can be reduced to the modern equivalents of these figures, the prospects of its development on a large scale would not seem to be particularly hopeful, from the national point of view.

If low-temperature carbonization is proved to be a feasible operation commercially, it would find its first and most natural application to the 35,000,000 tons of coal used for domestic purposes. Were this coal all carbonized, it would produce about 2,000,000 tons of fuel oil. The motor spirit produced would amount to about 100,000,000 gallons.

The capital expenditure required for the installation of carbonizing plant for 35,000,000 tons of coal per annum would be of the order of 30 to 40 millions sterling (\$175,000,000). A gross profit of 5s. (\$1.20) per ton of coal carbonized would provide 10 per cent for interest and 10 per cent for depreciation on this expenditure.

When coal is used for steam-raising under the best known conditions, it is obvious that there is little to be gained in thermal efficiency by any preliminary sorting out of the thermal units of the coal into fuels of higher availability.

*Extract from the James Forest Lecture on "Fuel Problems of the Future," delivered June 28 before the British Institution of Civil Engineers.

The Economy of Modern Grinding Methods

Preliminary Statement Regarding the High Cost of the Obsolete Grinding Plant and an Appeal to the Operator to Study Fundamental Principles of Reduction—
—Classification of Grinding Operations

By HARLOWE HARDINGE

GRINDING is a subject so broad and so involved that an attempt to cover the entire field in a short article would be a waste of effort. On the other hand, it is a process thought by many to be of little importance, as compared with others, in their plant. The general attitude taken toward grinding is that it is a necessary evil and that the operator might as well make up his mind that he is going to have trouble, and let the matter rest at that.

In the last few years there have been such strides made in simplifying and standardizing methods of grinding that the manager of the modern plant no longer considers grinding to be "the fly in the ointment" of an otherwise smoothly running plant. It is the aim of this article to point out why there has been so much trouble in the past and how it is possible to eliminate, to a great extent at least, the waste that is occurring in so many plants where materials of all kinds are ground.

The old hand-to-mouth method of operating that has been in existence in industrial plants throughout the country is gradually dying out and those in charge are realizing that modern equipment, although it may be more expensive than the old style in the initial cost, is far cheaper in the long run, and when once installed causes no trouble. In the old days the first cost was the chief consideration and the machinery soon ground itself to pieces and the operator found he was paying more each year for repairs than the original purchase price of the machine.

Business will soon be procured on a highly competitive basis. The manager whose main thought in equipping his plant is first cost rather than ultimate cost of operation will find that he is out of the running; he will not be able to compete with the man who figured on staying in business and operating at a minimum cost, not only for one year but for many years, with the same equipment. It is very gratifying to see that so many companies have forsaken the old ideas and have rebuilt or are redesigning their plants so as to be able to stand the close competition which is bound to come.

ACCUMULATION OF GRINDING MILLS

It was common practice several years ago for the millman to try first one style of equipment and then when a salesman came along who recommended another style, with its supposed marked advantages, he would either throw out the old equipment or install a new mill alongside the old, with the chances that the new mill would have little or no advantage over the old. After this was done several times and the plant was filled with all sorts of grinding devices, the operator would give up in disgust and absolutely refuse to entertain a new proposition. He would worry along with the equipment he had, continually buying repair parts and becoming thoroughly convinced that what he had was as

good as anything for handling his problem, even though he would admit he was shut down for repairs more than he would like to be. He would also excuse the situation by saying that no grinding equipment could run more than 75 or 80 per cent of the time on his particular material.

Based upon his experience with grinding equipment he had operated, he possessed strong ideas on the principle of grinding, and tried to make every problem substantiate his claims. This condition, while fast dying out, still exists in many fields, and it is in these fields that grinding in general is about fifteen years behind the times. It is just within this period that other methods have been worked out, so that now, unless these old-time operators and managers make a study of modern methods, they will soon find themselves out of the running. They must know something about grinding other than the ideas that have been forced upon them by the operation of the particular equipment they have used, in the particular way that they desired to grind.

GRINDING PRINCIPLES AND EXPERIENCE

A person may get his nose so close to the grindstone that he cannot see an obvious solution coming right to him, and cannot see how the operation, under other conditions, is at all analogous to his.

As a striking example of what a broader knowledge of grinding will do to help solve difficult problems, there was a case brought up recently by a wide-awake manager handling diamond-bearing clay, which had to be disintegrated in order to free the diamonds. This manager spoke of the trouble that was encountered due to the diamonds remaining in the mill longer than necessary, which resulted in a tendency to cause breakage. As this problem had never confronted the manufacturer of this particular grinding device before, there was no direct method, except by guesswork, of how to correct this trouble. By referring to the solution of a problem of grinding barytes containing a small amount of silica—which had a tendency to remain in the mill and be ground up, but which later by a simple adjustment was discharged without being ground—the problem of getting rid of the diamonds without breaking them was solved, and the operation made highly satisfactory. It is this application of one method to another problem which is directly responsible for the enormous strides which have been made in grinding methods within the last few years.

The matter boils itself down to just this: In order to keep abreast of the times the operator must study the fundamental principles of grinding in addition to those which he has evolved from his own experience. The operator must also know what he is buying and how it compares with other devices to do the same

work from all standpoints, particularly that of operating cost. When this study has been made, he will no longer be in the position that he was a few years ago when he installed equipment in a more or less haphazard manner, and trusted too much to the salesmen's theories, which are often warped, to apply to the particular device then being advocated.

EXCUSES FOR THE OBSOLETE PLANT

The following are some of the reasons why many operators have failed to standardize on grinding equipment and why so many plants are now out of date:

Pulverizing Usually a Side Issue. In many plants, grinding is not the main item of expense, or even if it is, it may not receive sufficient attention.

Principle of Grinding Not Comprehended. The operator usually evolves principles of grinding which are biased, and while correct to some degree, are not broad enough to allow him to get the most out of the equipment he has, to say nothing of getting the right sort of equipment to handle his particular problem.

First Cost Too Often Considered as Most Important. A very grave mistake is made when pulverizing equipment is bought mainly on first-cost basis, for the chances are it not only operates on the wrong principle but is inferior in design and construction and will be much more expensive to operate as compared with more costly machines offered at the same time.

Lack of Knowledge of Operations in the Same Field. While in some fields operators take full advantage of the information of the grinding done by their neighbor, operators in other fields show no interest in what their neighbor is doing and do not believe the information obtainable from their neighbor could possibly be of any use to them.

Lack of Interest in Other Fields of Grinding. The operator seldom takes much interest in other methods of handling grinding problems than his own, while if he were alive to the situation he might be able to apply the other man's method of handling his problem to his own and be much better off.

Methods He Is Now Using Made Money for Years. The operator often goes on the basis that equipment he is now using has made money for him for years. Why is it not just as good now? The question will of course be answered within the next year or two, if he is one of those who insists on using equipment purchased ten or twenty years ago.

Limited Experience. Very often the operator has grown up with his plant and has not had an opportunity of seeing how others handle the same or similar problems. As a consequence he goes along year after year, using the empirical methods he has evolved, which could almost certainly be improved with broader vision.

Making All Cases Apply to His Limited Understanding. If a problem comes up which is new to him, he will apply the principles he has evolved from his experience to this particular problem, and if his experience is limited, the chances are he will not be able to solve the problem as satisfactorily as the man who has made a broader study.

Unbiased Principles of Grinding Hard to Obtain. The user of pulverizing machinery is to be excused in a great measure for a lack of knowledge of grinding, as there is very little published on the subject. What information is published is either written from the

standpoint of one man's knowledge of a particular problem, which is limited in scope, or the information is obtained through salesmen, who unintentionally distort fundamental principles to suit their purpose.

Information obtained from other operators is valuable, as it is concrete evidence of what has been done under specified conditions. On the other hand it is often bad, first because it gives a biased viewpoint, especially when the use of the equipment for a special case has been subject to question by others, and second, because the operator using this equipment will try to prove his point and thereby substantiate his actions.

In some cases, especially where the field for the particular product being manufactured is limited, deliberate attempt is made to belittle the grinding equipment, even though it is operating with a high degree of satisfaction and efficiency, the object of this being to steer the competitor clear of equipment that is keeping production costs below the average.

TYPES OF GRINDING OPERATIONS

In order to give a slight idea of the enormous field of grinding, the table on p. 231 mentions some of its applications. Further details as to just how these problems are solved will be taken up in a later article. The object of this paper is to give a slight idea of the large scope of the modern grinding methods and why no two problems are alike.

Grinding, in general, may be classified under two main headings—wet and dry. Each of these may be subdivided into: Granular grinding, medium fine grinding, fine grinding, extremely fine grinding (with special applications), as shown in Table I.

In the case of granular grinding a product is desired with as small an amount of "fines" as possible, the average requirements calling for a product which passes a $\frac{1}{4}$ -in. opening and as much as possible remains on 10-, 20- or 30-mesh, as the case may be.

For medium fine grinding, most cases call for a product which passes a 20-mesh screen, the amount of "fines" produced being of little importance.

In the case of fine grinding, it is desired that as much fine material be produced as possible, commensurate with economical operation. Usually the specifications will run anywhere from 90 per cent through 100-mesh to 95 per cent through 200-mesh.

For extremely fine grinding, the specifications are very rigid and often call for a product so fine that it will all pass any screen manufactured. Therefore other physical tests must be resorted to, such as by microscope, feeling of grit between the teeth, by a spatula on glass or by a predetermined settling rate in water or air.

GUIDE FOR THE OPERATOR IN PURCHASING GRINDING EQUIPMENT

As no two grinding problems are alike, it is necessary to treat each separately and cover all the points which will affect the ultimate cost of operation.

First cost is important, but is secondary when compared to the cost of operation. Unless both are carefully considered, the operator is storing up trouble for himself in the months and years to come.

In considering grinding equipment of several makes, it is well to tabulate answers to the questions in each case, covering the main factors that are liable to determine the outcome of the purchase. These questions may be summarized as follows:

Is it the type of equipment to perform your work properly?

What is the total first cost of equipment and auxiliary apparatus f.o.b. factory?

What is the total cost of freight for equipment and auxiliary apparatus to go with this equipment, if any?

What is the cost of erection, including buildings, foundations, etc.?

What floor space is required?

What head-room is required?

Is the equipment self-contained?

Is it easy to inspect when located in the building as you have planned?

What power is required to start and what power to operate?

Is the equipment and lay-out designed so that it is dustless, if grinding dry or water-tight and clean if grinding wet?

What repair parts will have to be kept on hand?

What will be cost of repairs per ton of material ground?

What labor will be required to operate the grinding equipment? Will it have to be skilled and how much time must be allotted?

What percentage of operating time is assured after the equipment has been in operation one year?

Is the equipment simple in design and does it require constant attention to keep oiled or parts tight?

What facilities are there for feeding or discharging automatically?

Is the unit as a whole flexible—i.e., will it wear itself out if underloaded or overloaded?

What troubles are liable to follow, either in loss of production or otherwise, due to choking or jamming of working parts?

Has estimate of capacity been based upon actual conditions that you will maintain, such as maximum size of feed, fineness of product, moisture content and hardness of material?

In the old days (and in some cases today) an operator had no idea of what it was costing him to grind. All he knew was the total amount he spent each month for his entire plant, but he did not segregate the cost of labor, power, repairs and miscellaneous expenses to each operation. The old hand-to-mouth method is rapidly dying out. It is possible to estimate very closely what the total grinding cost will be.

Grinding costs are usually segregated as follows:

Power	Delays
Labor	Interest on investment
Supplies	Depreciation
Repairs	Miscellaneous

Some operators are not familiar with the method of figuring these costs, and the examples given in Tables II and III will be useful.

The first case shows typical itemized costs of a modern grinding device, pulverizing medium hard limestone at the rate of 15 tons per hour, grinding dry, the feed going to the mill all passing a 2-in. ring and the product all passing 20-mesh, with 50 per cent through 100-mesh. It must not be forgotten that this cost is based upon a given operating condition and that larger tonnages under the same condition will reduce the cost, and conversely, the cost will increase as the capacity and size of equipment are reduced.

The second case is a striking example of the cost of dry grinding by the older methods, many of which are being employed even today. The figures given are averages and do not cover any particular type of mill, but cover the same items based upon the same unit cost.

Under item "Interest on Investment" the same total amounts were used in each case. The cost of the mill itself for the new installation was assumed higher than for the old, but when accessory equipment, freight and all erection charges were figured in, the total cost was approximately the same.

The reader may not agree with the method of calculation throughout, but as comparison is being drawn, it

TABLE I. CLASSIFICATION OF GRINDING

DRY GRINDING

Granular Grinding

Carborundum, emery, silica and ganister rock.	For abrasives
Salt	For table use
Iron and metals	For recovery from gangue or waste.
Chemicals	For aid in chemical processes.
Grog.	For manufacture of tiles, porcelain ware, etc.
Mica and slate	For roofing.
Asbestos	For obtaining fiber

Medium Fine Grinding

Limestone	For asphalt filler and agricultural purposes.
Barytes and coal mixture.	For manufacture of paint / base.
Phosphate rock	For fertilizer.
Sulphur	For chemical compounds.
Iron and minerals	For concentration or separation by special processes.
Hard rubber	For manufacture of rubber composition.
Sawdust	For chemical purposes.
Cast-iron borings	For chemical purposes.

Fine Grinding

Limestone	For the manufacture of cement.
Clinker	For the manufacture of cement.
Coal — bituminous and anthracite	For burning under boilers, in kilns, driers, furnaces, etc.
Grain—various kinds.	For food purposes.
Feldspar	For pottery manufacture.
Mica	For use in tire trades.

Extremely Fine Grinding

Barytes	For use as a paint base
Filter cake	To prevent formation of lumps in further processes.
Grain	For best grades of flour for food.
Pigments	For the manufacture of paints.
Pumice stone and emery	For dental purposes.
Graphite	For pencils.
Talc	For paper filler, talcum powder, etc.

WET GRINDING

Granular Grinding

Ores	For extraction of minerals by jigging and table concentration.
Clay	For recovery of diamonds.
Graphite schist	For recovery of flake graphite from waste rock.

Medium Fine Grinding

Ores	For extraction of minerals by amalgamation and flotation processes.
Foundry waste	For reclamation of metal contained therein.
Iron pyrites	For manufacture of sulphur.

Fine Grinding

Ores	For extraction of metal by cyanidation.
Mica	For wallpaper trade.
Feldspar	For use in pottery manufacture.

Extremely Fine Grinding

Barytes	For paint base.
Carborundum and emery	For glass polishing.
Limestone	For manufacture of whiting.
Pigments in water	For manufacture of colors.
Pigments in oil	For manufacture of oil paints.
Ink	Incorporation of carbon and other materials in oil.

stands to reason that figures made up on the same basis for both methods will give comparative results.

Most engineers in figuring costs do not include all the items mentioned, especially that of "delays." This item is of considerable importance and one of the most difficult to figure. Some operators object to this from the

TABLE II. ESTIMATED COST OF GRINDING

Modern Type of Equipment	Old Type of Equipment
Power: 90-hp. at 2c. per kw.-hr. Hp. × cost per hp.-hr. = Cost per ton. Tons per Hour $90 \times 2 \times 0.746$ 15 = 8.95c.	Power: 150-hp. at 2c. per kw.-hr. $150 \times 2 \times 0.746$ 15 = 14.90c.
Labor: One man at 50% total time employed at 40c. per hr. Labor cost per hour = Cost per ton. Tons per hour $0.5 \times 40c.$ 15 = 1.33c.	Labor: One man at 100% of total time employed at 40c. per hour. 40 15 = 2.66c.
Supplies: Wear of grinding media 1/5-lb. per ton. Cost laid down at plant 6c. per lb. Cost per ton equals $6 \div 5 = 1.2c.$ per ton. Wear of lining 1/15-lb. per ton. Cost laid down at plant, 12c. per lb. Cost per ton equals $12 \div 15 = 0.8c.$ per ton. Total, per ton. 2.00c.	Supplies and Repairs: Assuming either old type of ball mill or high-speed pulverizer, average results show at least Per ton. 10.00c.
Repairs: Miscellaneous repairs, gears, bearings, etc., at \$800 per year. Assume 300 working days per year and 24 working hours per day. Cost per year in cents Tons per year = Cost of misc. repairs per ton. 800×100 $24 \times 300 \times 15$ = 0.74c.	Refer to above.
Delays: Time lost in breakage and delays, chargeable to mill at 6 days per year of 300 days. Cost of unground limestone \$1.50 per ton. Selling price of ground limestone \$3 per ton. All charges, except power and supplies, continue regardless of delays. Hours of time lost Total possible hrs. per yr. = Per cent of time lost. Selling price of product less operating costs (exclusive of delays), less cost of unground limestone = Profit per ton. Difference between profit per ton and power and supply costs per ton, multiplied by % of time lost % of time operated = Cost of delays per ton. $6 \times 24 \times 100$ 300×24 = 2% time lost. Profit = $300 - 16.11 - 150 = 133.89c.$ per ton. Cost = $(133.89 - 10.95) \times 2$ 98 = 2.54c.	Delays: Time lost due to breakage and delays chargeable to mill, 20% of total possible operating time per year of 300 days. Worth of unground limestone \$1.50 per ton. Worth of ground limestone \$3 per ton. All charges, except power at 14.90c. per ton, continue regardless of shutdown. Per cent of time lost, 20%. $300 - 32.52 - 150 =$ profit 117.48c. per ton. $(117.48 - 24.9) \times 20$ 80 = 23.10c.
Interest on Investment: Cost of mill erected complete with all accessories, including freight, foundations, labor, etc. (but not building cost), \$20,000. Cost × interest rate per year Tons ground per year = Cost per ton. $20,000 \times 0.06 \times 100$ $15 \times 24 \times 300$ = 1.11c.	Interest on Investment: Cost of mill erected complete with all accessories (including freight, foundations, labor, etc.), but not building cost, \$20,000. Cost × interest rate per year Tons ground per year = Cost per ton. $20,000 \times 0.06 \times 100$ $15 \times 24 \times 300$ = 1.11c.
Depreciation: Cost as above \$20,000 at 8% per year. $20,000 \times 0.08 \times 100$ $15 \times 24 \times 300$ = 1.48c.	Depreciation: Cost as above \$20,000 at 10% per year. $20,000 \times 0.1 \times 100$ $15 \times 24 \times 300$ = 1.85c.
Miscellaneous: Oil, grease, etc. 0.5c.	Miscellaneous: Oil, grease, etc. 2.00c.

standpoint that they run their plant only twenty hours out of a 24-hour day, or if running on a 10-hour day basis, figure on getting their required capacity in eight hours and therefore this item would not enter into their calculations. Why do they figure on running only twenty hours out of twenty-four, or eight out of ten? Why not figure on running closer to the limit, thus increasing the capacity and enabling the plant to make more money, assuming, of course, that the other equipment in the plant, if any, is able to handle this increased

TABLE III. SUMMARY OF COMPARATIVE COSTS

	Modern Type of Equipment	Old Type
Power.....	8.95c.	14.90c.
Labor.....	1.33c.	2.66c.
Supplies.....	2.00c.	10.00c.
Repairs.....	0.74c.	23.10c.
Delays.....	2.54c.	1.11c.
Interest on investment.....	1.11c.	1.85c.
Depreciation.....	1.48c.	2.00c.
Miscellaneous.....	0.5c.	
Total cost per ton.....	18.65c.	55.62c.

capacity? Those who realize the value of continuity of operation have made provision for obtaining a definite capacity by installing spare equipment. This is certainly cheaper than running the old style of grinding equipment up to capacity, and the moment any mill is shut down the whole plant is retarded by the amount of loss in production in the grinding department. With modern equipment, there is no use in figuring on a large "factor of safety." Instead of running 80 per cent of the time, a unit will run 90 to 98 per cent of the time. Operators have been so accustomed for years to figure on a large percentage of lost time that they take this loss for granted. This condition was true in the mining industry a number of years ago, but of recent years the equipment has been so developed and standardized that 97 to 98 per cent running time for the grinding equipment is not unusual.

The value of the new method is readily appreciated when it is seen how long it would take to pay for the entire new installation out of the savings in the cost of grinding.

This is shown in Table IV.

TABLE IV. SAVINGS IN COST OF GRINDING

Total cost of installing new equipment.....	\$20,000.00
Scrap value of discarded old equipment.....	2,500.00
Net cost of new equipment.....	\$17,500.00
Grinding cost per ton of old system.....	0.5562
Grinding cost per ton of new system.....	0.1865
Saving in cost per ton over old system.....	0.3697
Saving per day = $0.3697 \times 15 \times 24$ or.....	\$133.20
Saving per year = 133.2×300 , or approximately.....	\$40,000.00
Time required to pay for new installation out of savings, due to decreased operating expense, $17,500 \div 40,000 \times 12 =$ 5.25 months.	

In other words, in one year's time the entire new installation is paid for with an additional net saving of approximately \$22,500. It is difficult to believe that such a saving is possible, but the figures are based upon concrete evidence, submitted by several managers and operators who have replaced old equipment with new.

There is absolutely no doubt that the time has come when the operator must be a specialist in his line and make a comprehensive study of conditions in his plant, just as the modern executive has evolved a simple method of keeping track of what is going on about him and has made a special study of the specific points of vital interest, in order to handle his business efficiently. New York City.

Plastic Calcined Magnesite and Oxychloride Cements*

Physical Tests Showing and Factors Influencing the Properties of Oxychloride Cements — Suggested Specifications Include Reduction of Magnesia 97 per Cent Passing 100 Mesh and 75 Through 200 —Chloride Solution 22 Deg. Bé.—Initial Set From One to Eight Hours

By M. Y. SEATON

THE magnesium oxychloride industry dates from the discovery by Sorel, in 1867, of the cementing action of a mixture of magnesium oxide and a solution of magnesium chloride. Sorel found that the cement produced was enormously strong and had very high binding power—that is, that it would allow of dilution with a very large quantity of aggregate and still produce a product of high strength. It was particularly noted that it would bind sawdust in satisfactory fashion to a hard, tough mass. This could not be accomplished by any of the usual cementing mediums known at that time.

The exact chemical constitution of Sorel's cement is still an open question. It seems probable that it is only partly a definite oxychloride, probably $3 \text{ MgO} \cdot \text{MgCl}_2 \cdot 10\text{H}_2\text{O}$, and that this is mixed with solid solutions of indefinite composition. Efforts to regulate the composition of a mix in such fashion as to keep the oxide-chloride ratio constant at that which holds for some particular oxychloride have not been reflected by any striking results from a strength or soundness standpoint.

The commercial possibilities of Sorel's cement were very soon recognized and within a comparatively few years after his invention the construction of floors composed of sawdust, wood flour and sometimes siliceous aggregate, cemented with magnesium oxychloride, became quite common in Germany and in France. Various difficulties in the preparation of satisfactory mixes were experienced, but the industry developed normally and later spread to this country. It is found possible to secure properties in a flooring using an oxychloride cement binder which cannot be obtained by the use of any other flooring material. The product accordingly has taken its place as a more or less standard building material. Oxychloride, or, as they are commonly called, "composition" floorings require highly skilled workmanship in their application, but numerous organizations are now in a position to lay such floors. The development of exterior stuccos in which magnesium oxychloride is the binding medium is more recent. Sorel's original statements as to the water-proofness of his cement have not been entirely confirmed and there was for a long time a real doubt as to the permanence of such stuccos. Experience has shown, however, that, provided the raw materials are of proper quality and are properly mixed, a sound and permanent stucco will result.

In the preparation of any oxychloride cement, three classes of raw materials are required: aggregates, magnesium chloride, and magnesium oxide. The aggregates employed include sand, ground sand or silex, marble or limestone dust, talc, china clay, sawdust and

wood flours of various grades, asbestos fiber, and pulverized cork. The fineness and the percentage of voids in sand, the fineness of the various fine fillers, the type of wood and the particle size of wood flours and sawdust, the fiber length of asbestos, and the fineness of granulated cork give indications as to their value. The magnesium chloride employed is recovered from natural brines or salts in the Stassfurt district, or from Michigan, Utah or California in this country. The usual product is either a solid or granular material containing in the neighborhood of 98 per cent $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ and less than 2 per cent of calcium chloride, of magnesium sulphate, or of sodium chloride. Chemical analysis clearly indicates its quality. The magnesium oxide required is essentially all prepared from natural magnesite, large deposits of which occur in Greece, Austria, Venezuela and in the states of Nevada, Washington and California. The term "plastic calcined magnesite" is in a sense a misnomer. Magnesite after being calcined is obviously no longer magnesite, but is magnesium oxide or magnesia. Inasmuch as the magnesium oxide used by the oxychloride industry is generally prepared by the heating of natural magnesite rock, the term has gained such standing with consumers that it will be used unchanged throughout this paper. "Plastic magnesia" or "caustic magnesia" are occasionally employed in the same sense. The testing of this product has proved one of the most troublesome points encountered by producers of oxychloride cements.

PHYSICAL TESTS OF OXYCHLORIDE CEMENTS

It is obvious, of course, that the value of any plastic calcined magnesite lies in its ability to form sound, strong and permanent oxychloride cements when used in proper mixtures and that only tests which are indicative of its ability to fulfil this function will throw light on its quality. We must consider first, then, the question of physical tests of oxychloride cements.

Selection of a standard testing mix for oxychloride cement investigations is rather troublesome. Entirely unsatisfactory results have been obtained by attempting to test mortars containing only sand as an aggregate, that is, by following the general practice used in testing portland cement. The reason for the trouble is not far to seek. The mortars and the concretes used in portland cement tests approximate in composition mixes used in the field. It is quite rare for a commercial oxychloride cement to contain only sand as an aggregate, or at least only sand of the character of the sands usually used in cement testing. The usual oxychloride stucco is either prepared from an excessively fine sand or contains a considerable amount of fine aggregate, most commonly ground silica or silex. It is found, in fact, that best results can be obtained only

*Read before the American Society for Testing Materials, Asbury Park, N. J., June 22, 1921.

when such a fine aggregate is used in an oxychloride mix. An elaborate series of investigations has indicated that most concordant test results are obtained in a mix which contains as high as two parts of silex to five of sand. Such a mix requires the use of only a comparatively small amount of calcined magnesite, 12½ per cent of the total mix being sufficient. The standard testing mix referred to throughout the remainder of the paper will be one containing one part calcined magnesite, two of silex—the material known commercially as 120-mesh silex being used—and five of standard Ottawa sand. When the question of adoption of a standard floor mix is considered, even more difficulty is encountered. So many different types of floors are laid, varying from soft and resilient to hard and stonelike, that any one mix will represent but a comparatively small proportion of the total actual installations. There are definite relations between the results obtained on flooring and on stucco mixes when used with various magnesites, so we will consider at length only tests on the standard stucco mix.

The data necessary for determination of quality of an oxychloride cement can be obtained from tests for strength, volume change, setting time and permanence of the product.

STRENGTH TESTS

Four types of strength tests have been studied—namely, tensile, compressive and cross-bending strengths, and resistance to abrasion. No particular comment is needed on tests for tensile or for compressive strengths. The ordinary standard size briquet for tensile tests and the usual cubes or cylinders employed for mortar compression tests can be used to good advantage. Such tests, although throwing much light on the properties of oxychloride cements, sometimes do not check field results. It should be recognized that oxychloride products are used at present only as comparatively thin surface coatings, never being employed in mass work of any type. Neither briquets nor compression cubes or cylinders can be aged under conditions comparable with the aging of such thin coats of flooring or stucco. Especially during the early life of the cement, contact with air exerts a considerable influence on its rate of gain of strength.

It has been considered important, accordingly, to work mainly with test specimens approximating in shape a section from the coatings as applied in practice. Excellent results have been secured from flat bars ½ in. thick, 2 in. wide and 24 in. long. These bars can readily be prepared in suitable steel molds and, after proper aging, can be tested in a simple cross-bending machine in which the load is applied by running shot into a cup supported on the bar. An ordinary plasterers' trowel is used in preparing the test specimens and the influence of various methods of troweling can be readily studied. Flat bars of this type, besides more closely approximating field aging conditions for stucco or flooring mixes, allow also of determination of modulus of elasticity and of the making of water resistance tests, which latter cannot be conveniently made on other forms of specimen.

For flooring mixes, there is no inherent reason to suppose that a direct relation between tensile strength and resistance to abrasion need exist. Some interesting data on the abrasion resistance of various composition floors have been obtained by rotating a set of steel cubes weighing about 5,000 g. over the

surface of the floor while a slow stream of fine silex is fed onto the surface to serve as abrasive material. The depth of the impression in the floor is readily obtained from a small measuring bridge supported on points outside the abraded area by which a map of the floor surface can be drawn.

VOLUME CHANGE

The volume change, or more exactly, the linear expansion or contraction of a test specimen, is of decided importance in a study of oxychloride cement quality. Two methods for the measurement of this property have been considered. One consists in the preparation of bars 1 in. square and 10 in. long, which have metal plates imbedded in their ends. These bars can be removed from the molds at about the period of final set and measured by a large micrometer. Such bars, however, do not allow of determination of change in length during the early ages of the material—that is, during the period before final set—as they are too weak to be handled at such a time. Inasmuch as a certain amount of difficulty with cracking of stucco and of flooring mixtures has been encountered during this early period, somewhat more satisfactory results have been obtained by measurement with the Berry strain gage of the movement of reference points inserted in a ½-in. bar of stucco or flooring mix which is formed on a sheet of waxed paper and need not be disturbed during testing. Such measurements can be begun at the period of initial set.

SETTING TIME

Setting time of oxychloride mixes can be determined by the usual Vicat or Gillmore needles. Certain complications are introduced by the fact that mixes containing aggregate must be tested. The results on neat mixes of calcined magnesite and magnesium chloride solution are not found to be comparable with results obtained from the use of the same magnesite in the usual flooring or stucco composition. Some difficulty in determining definitely the end point of setting time may be encountered on account of the presence of sand in the mixes being tested, but determinations are still fairly accurate. Where a large number of determinations are to be made, the Hill setting-time machine, which automatically raises and lowers a set of Gillmore needles onto an extremely slowly moving pat of the oxychloride mix, has been found to give good results. With a known rate of movement of the pat, setting time can be determined by measuring the length of the series of impressions from each needle.

PERMANENCE

Inasmuch as all oxychloride products are submitted to periodic wetting either from the weather, in case of a stucco, or from scrubbing, in case of a flooring, some data on water resistance of oxychloride mixes are of value. The flat bars mentioned above allow of making a water test comparatively easily. They can be placed behind a perforated grid which protects their backs from direct contact with water and sprayed with a gentle mist of water directed against their faces. Strength can be determined after various periods of wetting and of subsequent drying. A satisfactory water test has been found to consist of spraying 14-day-old bars for three successive 24-hr. periods with 24-hr. drying periods intervening, finally testing the bars wet and after two days' additional drying in comparison with the usual test on an unsprayed bar.

Various factors will influence the value of the test results obtained by any of the methods noted above.

Consistency of the mortar will influence strength in the same direction in which consistency variation influences strength of portland cement mortars. The effect is very much less marked, however. With portland cement mortars, an increase in consistency from normal to 125 per cent of normal gives a lowering in strength to about 65 per cent of normal. A similar increase in consistency of an oxychloride cement mortar gives a decrease in strength of 93 per cent of normal. There is not as great danger, accordingly, of poor results being obtained from excessive addition of chloride solution with oxychloride cements as there is from the use of too much water with portland cement. On this account, too, the usual schemes of definition of aggregate quality which depend directly or indirectly on the amount of water required to make a plastic mix with the aggregate in question entirely fail when applied to oxychloride cement mixes.

The strength of the magnesium chloride solution has great influence on the properties of oxychloride cement. Fig. 1 gives the results obtained from an average oxychloride stucco mix by increasing the strength of magnesium chloride solution progressively. It is seen that satisfactory results cannot be expected from dilute chloride solutions. The curves might indicate that better cements would be obtained as the specific gravity of the chloride solution was increased to a very high point. Other factors, however, must be studied before such a step can be considered. With chloride solution strengths above 24 deg. Bé., undue expansion effects develop. The optimum concentration of the magnesium chloride solution appears to lie at 22 deg. Bé. A certain amount of field work is done with chloride solutions of from 18 to 20 deg. Bé., but the slight saving in magnesium chloride effected by this practice cannot be justified in view of the decided advantage to be gained by the use of somewhat stronger chloride. The reason for the use of weak chloride is frequently said to be the fact that such chloride solutions will make an oxychloride cement which sets slower. This is entirely opposed to the results found from determination of setting time of a series of mixes in which

chloride strength is varied. From the practical man's standpoint setting time of an oxychloride stucco is of interest inasmuch as it influences the behavior of the stucco when dry pebble dash is applied to it. A material which sets too fast resists the penetration of the pebbles. Careful tests have shown that although there is a slight difference in favor of a stucco prepared with weak chloride when the question of dash penetration is considered, this difference is only in the neighborhood of 10 per cent, an amount which is not observable in actual practice.

INFLUENCE OF THE CHARACTER OF THE AGGREGATE

The character of the aggregate influences the various properties of an oxychloride cement in a rather complex way, and the question can no more be covered in a short space than can that of the study of aggregates for use in portland cement concretes. In general it may be said that the use of fine aggregate is essential for the attainment of high strengths and good water resistance. The mechanism of the setting reaction with oxychloride cement is quite different than with portland cement. When portland cement sets, the small particles surround themselves with a shell of reaction product, but the center of each cement particle remains unchanged. In a sense, then, portland cement furnishes its own fine aggregate. With oxychloride cements, provided the calcined magnesite is reasonably finely ground, each particle of magnesium oxide completely enters into reaction. If the reaction product is called on to fill the comparatively large voids between sand grains, a mass of inferior strength will result.

However, if a fine aggregate is introduced which will itself enter the voids between sand grains, the oxychloride cement will need only to coat these particles of fine aggregate and to fill the much smaller voids which would result and much higher strengths and permanence will be secured. Here, as in the case of portland cement mortars or concretes, the cementing material is the weakest portion of the set mass and if it can be reduced to a minimum, the physical properties resulting will be more desirable. When very fine magnesites are employed, the amount required for production of strong cements can be reduced to a surprisingly low figure, 4 or 5 per cent only being required in a mixture in which the coarsest aggregate is a comparatively fine sand. If an oxychloride concrete were to be formed, the amount needed would be still smaller.

Curves giving strength of mixtures of various composition, in all of which the same magnesite and same strength of chloride solution were used, are given in Fig. 2. They indicate strikingly the advisability of the addition of fine aggregate. It should be noted that the influence of fine aggregate on wet strength is even greater than on dry strength. Mixes without fine aggregate often disintegrate completely on wetting.

Storage conditions during the aging of oxychloride test specimens of any type must be carefully regulated. Storage in air is always employed. The temperature must not vary more than 10 deg. F. from a standard of 70 deg. F. and humidity not over 15 per cent from a standard of 50 per cent relative humidity if concordant results are expected. High temperature or low humidity increases rate of gain of strength and greatly accelerates setting; low temperature and high humidity have the reverse effect.

The quality of commercial calcined magnesite exerts

FIG. 1. RELATION BETWEEN SPECIFIC GRAVITY OF CHLORIDE SOLUTION AND TENSILE STRENGTH OF 1:2:5 OXYCHLORIDE MIX

FIG. 2. STRENGTH AT 14 DAYS OF OXYCHLORIDE MIXES CONTAINING CALCINED MAGNESITE, SILEX, AND SAND

Ratio of silex to sand varied, but MgO content of each mix held constant.

a tremendous influence on the properties of oxychloride cements. Certain magnesites appear on the market which will not give a satisfactory product no matter what attention be paid to other details of mix composition. The usual tests of magnesite quality which have been applied in the past have consisted of a chemical analysis of the calcined product. In general, limits for ignition loss, calcium oxide, silica and magnesium oxide have been written into specifications. Users of this product have come to realize during the past few years, however, that their chemical analysis specifications were not insuring them a magnesite of high quality. Some results which bear out this point are shown in Table I.

Study of several hundred commercial magnesites has indicated that there is only one factor determinable by chemical test which exerts a definite influence on the character of the cement. This is the percentage of the active lime. The amount of this constituent present bears no relation to the content of total lime in the magnesium oxide. Active lime can be determined by agitation with dilute magnesium chloride solution and determination of the amount of calcium chloride introduced into the solution. Unfortunately, it is found that the relation between strength, permanency and active lime content is traceable only when average figures covering many magnesites are examined. Other factors play so important a part in regulating oxychloride cement strength that the relation does not appear when test results on individual samples are examined.

The explanation of the wide discrepancy between chemical analysis and physical test results is found in the fact that the time-temperature history of the calcining procedure is of vital influence on the reaction between magnesium oxide and magnesium chloride, although it is not reflected in any major change in analysis. Widely varying results can be secured from samples of calcined magnesite from the same rock.

SUGGESTED SPECIFICATIONS

Fairly satisfactory results can be obtained in study of magnesite quality if reliance be placed on purely physical tests. A determination of fineness is unquestionably of value. At least 97 per cent of the material should pass a 100-mesh screen and at least 75 per cent

a 200-mesh screen. Calcined magnesite is a comparatively easy material to grind and it is very probable that this fineness can be greatly increased and quality accordingly improved without introducing serious manufacturing difficulties. Coarse magnesite results in abnormal expansion of the cements prepared from it. The magnesite, if of satisfactory fineness, should be used in a standard oxychloride mix, preferably the one magnesite, two silex, five sand composition previously mentioned, and further tests carried out on this material. The specific gravity of the chloride solution used should be 22 deg. Bé.

The plastic oxychloride mortar should not show initial set within an hour. It should attain final set within eight hours. A 2-hr. minimum for initial set is preferred by some workers while some will consider the 8-hr. maximum for final set unduly long. The first limits, however, are about those met by average commercial calcined magnesite. Modulus of rupture on the flat bars previously described should be at least 550 lb. per sq.in. at one day and at least 1,000 lb. per sq.in. at seven days.¹ Oxychloride cements from average magnesites will give figures much higher than these. Limits on expansion and contraction are exceedingly difficult to set but it is probable that a magnesite which shows over 0.3 per cent contraction or expansion within twenty-four hours after initial set in the mix specified should be considered as of questionable quality. Limits for water resistance are also hard to set. Unless the oxychloride cement made from a particular magnesite shows a wet strength after the standard spraying procedure of at least 30 per cent of its dry strength, however, some doubt as to magnesite quality should be felt.

A calcined magnesite which meets the requirements suggested will certainly be of at least average quality. Much better material than that indicated can be secured when greater attention to the preparation of the calcined product is given by the various producers. Co-operative work is now under way which should lead to the establishment of more definite limits for the various factors discussed, probably resulting in the issuance of definite specifications for plastic calcined magnesite within a year or so.

The oxychloride industry is one of remarkable latent possibilities. It has suffered seriously from lack of attention to the quality of the raw materials used and from lack of knowledge of the basic principles of mix preparation. As more data on both of these points become available, there is little question that oxychloride cement products will take their place as standard construction materials for certain definite uses.

¹On 3x2-in. bars, broken on 20-in. centers, the modulus of rupture will average 2.2 times the tensile strength.

Hardwood-Distillation Industry—III

Discussion of the Problems Encountered in the Separation of Commercial Products From the Mixtures of Wood Distillates and of the Difficulties Encountered in the Distillation of Sawdust*

By L. F. HAWLEY†

THE problem of obtaining commercial products from the mixtures of wood distillates is usually taken up from the standpoint of producing especially acetate of lime and methanol from the pyroligneous acid and of separating the different oils contained in the tar.

It has been stated previously (p. 197) that the wood distillates when condensed give two crude products—namely, pyroligneous acid and tar—that gravity and solubility are not sufficient for their complete separation, that some constituents of the tar are found in the pyroligneous acid and *vice versa* and that their complete separation can be realized only by fractional distillation. The first operations, therefore, are the separation of the tarry material from the pyroligneous acid and the freeing of the methanol and acetic acid from the settled tar. If the tar is to be distilled in a fire still, the removal of the acid and methanol is made a part of that process, otherwise a steam distillation only is used.

The first apparatus used in refining the mixtures of wood distillates were fire stills heated by the direct heat from a firebox underneath. These stills required very careful control, and only workmen with considerable experience were able to obtain good results with them or even to operate them with safety. All of the stills used in the refining process, except the fire stills for tar, are now heated by steam coils, which are much easier to regulate and which give better results due to less superheating of the product.

PRODUCTS OBTAINED BY WOOD TAR DISTILLATION

On distillation the wood tar may be separated into products of considerable difference in their chemical and physical properties.

The first parts of the distillate, the light oils with boiling points up to 200 deg. C., have specific gravities less than unity and contain practically no phenols. These light oils are very complex and have been studied chemically by G. S. Fraps,¹¹ who investigated a commercial "wood oil" to determine its prominent chemical constituents. Fraps found that this oil contained a series of aldehydes, ketones and acids of the formaldehyde, acetone and acetic acid series respectively, the acids occurring mostly in the form of methyl esters. These constituents, however, are only the more active ones, and the less active compounds, apparently complex hydrocarbons, were not studied. No exact quantitative determinations were made, and the compounds identified probably constituted only a small proportion of the total oil.

The heavy oils from wood tar have also been studied in some detail, but only the phenolic bodies soluble in alkali have been identified. About sixteen phenolic bodies with boiling points between 178 and 285 deg. C. have been detected, but no figures have been given in regard to the percentage composition. It is noticeable that all these compounds are either straight phenols or methyl ethers of phenols. Although phenol itself and the cresols have been detected in wood tar, these occur only in very small quantities, the high-gravity and high-boiling methyl ethers being the main constituents. This is one respect in which hardwood tar differs from coal tar—namely, that phenol and the cresols are not present in considerable quantities.

Benzene and xylene have been reported as occurring in hardwood tar or tar oils; but although they may be present in small quantities, they are not of commercial importance.

That part of the heavy oils which is insoluble in alkali has never been studied, and there is no information available in regard to its probable composition. It does not, however, contain naphthalene or anthracene in appreciable quantities like the coal tars.

The residual pitch has never been studied from the chemical standpoint, but from its general properties it must be very complex chemically. A hard or soft pitch can be obtained, depending on the amount of heavy oils left undistilled in the pitch.

When distilling with steam a product known in the market as "wood oil" is obtained. This oil naturally varies with the amount of steam used in the distillation, but practically always contains all of the light oils previously mentioned, and in many cases considerable quantities of the heavy oils with boiling points above 200 are also included.

USES FOR WOOD TAR DISTILLATION PRODUCTS

From the discussion of the composition of the tar it can be seen that numerous different products could be made by variations in the method of separating, redistilling and drying the fractions of tar oils.

The light oils are a very good solvent for some purposes; the heavy oils are valuable for stains, disinfectants and preservatives, or as a raw material for the manufacture of beech-wood creosote; and the pitch has been used as a waterproofing and insulating material. Various combinations of light and heavy oils and pitch have been used for flotation oils, and this is the one general use to which hardwood tar and tar products seem to be especially adapted.

The distillation of hardwood tar in fire stills is a comparatively new process, but it has been very successful and there is a chance here for an increase in the value and number of hardwood-distillation products.

ACETATE DRYING FLOOR OVER THE OVENS

The pyroligneous acid freed of the tar it contained is neutralized with lime in order to form a non-volatile acetic acid compound from which the volatile methanol can be separated completely by distillation. After this neutralization the pyroligneous acid turns very dark, and non-volatile impurities are formed which contaminate the acetate of lime. The methanol is removed by distillation and the impure solution of acetate of lime remains behind. This impure solution is evaporated and dried to the commercial product called "gray acetate of lime."

Until within a few years some crude pyroligneous acid was used directly, when, after neutralization with lime, evaporation and drying, a product containing tarry impurities was obtained known as "brown acetate of lime."

As calcium acetate is more soluble in cold water than in hot, it is not possible to crystallize this salt by the usual methods. The impurities present also prevent the formation of good crystals on drying, and the finished material resembles a gray granular powder without crystal form.

There are many fine points in the neutralization of the distilled pyroligneous acid with lime which have never been properly studied. In commercial practice the neutralization is usually carried to a point which gives the best acetate of lime. If the neutralization is carried farther or not so far, difficulty is found in preparing a granular acetate, since there is a tendency for the material to separate out in a hard crust on the bottom of the evaporating pan instead of forming the usual granular crust on the surface of the liquid.

Since the pyroligneous acid contains both acetic acid and methanol, it must also contain a definite proportion of methyl acetate according to the equilibrium between the quantities of water, methanol and acid present. When the pyroligneous acid is neutralized, the methyl acetate is hydrolyzed to methanol and acid, but this takes place slowly and in most cases there are considerable amounts of methyl acetate still undecomposed in the distillate. This slow hydrolysis accounts for the fact that completely neutralized pyroligneous acid will become acid again on standing.

It might be possible to obtain slightly higher yields of methanol and acetic acid by making sure that the hydrolysis is complete before distilling the neutralized liquor, but if this must be done at the expense of difficulties with the quality of the acetate it is not considered to be worth the effort.

ACETATE SLUDGE

When the distilled pyroligneous acid is neutralized with lime, a considerable quantity of insoluble material settles out at the bottom of the tank. This so-called acetate sludge contains insoluble impurities from the lime and also insoluble organic compounds precipitated or polymerized by the neutralization of the liquid. This sludge was formerly settled out from the acetate liquor and thrown away without any serious attempt to wash it. It was soon found, however, that appreciable amounts of acetate of lime were being lost with the sludge, and various methods of washing have now been introduced. In some of the larger plants mechanical filters of different kinds are now used to remove the last traces of acetate from the sludge.

EFFICIENCY IN THE USE OF THE HEAT REQUIRED FOR REFINING

Since the refining of the hardwood-distillation liquors consists normally of several redistillations of the ordinary crude liquor, there is a chance to save considerable steam by the use of the principle of multiple-effect evaporation or in the use of exhaust steam for evaporating at reduced pressure. The multiple-effect principle has been applied in several ways. Triple-effect evaporators have been used on the green liquor or crude pyroligneous acid and also on the neutralized acetate liquor. A double-effect evaporation has been obtained by using one evaporator heated by steam for distilling the crude pyroligneous acid and then using the vapors from this evaporator for heating the acetate liquor in another evaporator.

Various types of evaporators have been used, and we have recently seen in operation some Klar ten or twelve years ago, aremba evaporators of copper with vertical tubes for use on the pyroligneous acid, Zaremba iron evaporators with horizontal tubes for use on acetate liquor, Buffalo Foundry & Machine Co.'s inclined-tube triple-effects and Badger evaporators for the double-effect combination in which the vapors from the pyroligneous acid are used to heat the acetate liquor.

DIFFICULTIES ENCOUNTERED IN THE USE OF EVAPORATORS

Varying results have been obtained, but the common objection to evaporators is the difficulty caused by the deposition of some form of tar either inside or outside the evaporator tubes. In one place the first-effect evaporator in which the crude pyroligneous acid was distilled gave a great deal of difficulty by the deposit of tar or pitch on the outside of the tubes. This, however, was finally avoided by allowing a part of the settled tar to flow into the evaporator along with the pyroligneous acid, the oils in the tar apparently dissolving the pitch from the tubes. In other cases, however, the crude pyroligneous acid has been evaporated without the presence of the settled tar and it is claimed that no difficulty has been encountered in fouling the tubes. In some places where there is no difficulty in the first-effect the vapors carrying over from this effect

seem to form a deposit on the inside of the tubes of the second-effect, and considerable trouble has been caused in this way. There seems to be no general agreement on the subject of the difficulties of tar deposition and how they may be best avoided, but it seems to be the general rule that evaporators working on wood-distillation products must be so constructed that the tubes both inside and outside can be readily cleaned.

When multiple-effect evaporators are operated at all efficiently there is a great saving of steam over the ordinary evaporation processes. It must be remembered, however, that the ordinary copper still is much simpler in construction and operation and is cheaper than the multiple-effect evaporator, and in cases where the cost of fuel is not high these points may make up the difference in steam efficiency. In one place a single-effect evaporator was in use on the crude pyroligneous acid and was heated entirely by exhaust steam. This evaporator was being used in place of four of the

MULTIPLE-EFFECT EVAPORATORS

ordinary copper stills which required pressure steam for their operation. This gives a good example of the possibility of steam economy in the refining of wood-distillation products.

SEPARATION OF THE METHANOL

Formerly the separation of the methanol from the neutralized pyroligneous acid was accomplished by continued redistillation in a series of ordinary pot stills without any kind of fractionating column. The first fractionating devices used in connection with this operation were the so-called Burcey pans, by which a certain amount of dephlegmation and fractional condensation were obtained. These Burcey pans were in use in most of the crude plants and were efficient enough, so that little difficulty was encountered in obtaining most of the methanol from the crude liquor in the form of crude 80 per cent methanol in one or two distillations. Column stills have replaced the Burcey pans in many plants with considerably increased efficiency, but a few of them are still in operation.

In places where triple-effect evaporators are used, the neutralized acetate liquor is usually run through a

continuous column still for the removal of the crude methanol before the liquor is run through the evaporators.

The use of column stills, particularly continuous stills, in concentrating the methanol is more efficient than the usual method of distilling the neutralized liquor in a lime-lee still and then concentrating the distillate from this still.

Continuous stills for the removal of the alcohol from the neutralized liquor are coming more and more into use and apparently give very satisfactory service.

In some places deposits of tar or pitch are formed in certain sections of these stills, but they do not often have to be stopped for the purpose of cleaning.

EFFECT OF THE PRESENCE OF METHYL ACETATE IN THE METHANOL LIQUOR

The effect of the presence of methyl acetate in the methanol liquor is of some importance on account of its effect on the determination of the percentage of methanol, which is always made by specific-gravity methods. Methyl acetate has a very high gravity in comparison with methanol, although its gravity is slightly less than that of water. On this account, if large quantities of methyl acetate are present, the determination of the value of the methanol by gravity is not correct, since the methyl acetate is not determined in proper proportion by gravity determination. Methyl acetate persists in the refining operations and is found in the final products of the separation of methanol.

BETTER QUALITY OF METHANOL

The quality of the refined methanol has gradually increased as demands were made for a better product and as experience in refining increased. The first refined methanols were of very poor quality, having considerable color and a very disagreeable odor. Since this product was used largely as a solvent, it was not necessary to prepare a pure alcohol, and although the color and odor were gradually improved, considerable quantities of acetone still remained in the refined alcohol. This is due to the fact that methanol forms with acetone a constant boiling mixture which cannot be separated by the most careful fractional distillation methods.¹² Fortunately, however, this constant boiling mixture has a high proportion of acetone which makes it possible to obtain by commercial distillation a very pure methanol, although the acetone separated from it contains also considerable quantities of methanol. Methyl acetate forms similar constant boiling mixtures with both methanol and acetone.¹³ At the present time, methyl alcohol without color or disagreeable odor and with only traces of acetone is produced in large quantities.

It may be desirable at this point to call attention to an error which constantly occurs in the literature on wood-distillation processes. A series of compilers, who have obtained their information from the printed page instead of from laboratory or plant, have handed down from one to another the tradition that acetone is separated from methanol in commercial refining plants by chemical methods. The methods mentioned are usually the formation of chlorine addition products of the acetone or the formation of a compound of calcium chloride with methanol from which the acetone can be removed by distillation. Although Klar, in 1910, was

¹²Haywood, *J. Phys. Chem.*, vol. 3, p. 349 (1899).

¹³Ryland, *Am. Chem. J.*, vol. 22, p. 384 (1899).

very emphatic in denying that these processes were then used commercially or had been used for years, occasionally one of these chemical methods for refining methanol will be mentioned in the literature as a modern commercial method.

EVAPORATION AND DRYING OF ACETATE OF LIME

The common method of handling the acetate liquor, after the methanol has been distilled from it, is to evaporate in shallow, steam-heated, iron pans and then dry the thick residue from these pans on the drying floor built on top of the retorts. In the case of the kiln plants this drying floor was especially built for heating by waste heat or by a special firebox. This process required pressure steam in the evaporating pan and considerable labor in operating the pans and in raking the acetate on the drying floor.

New methods have been introduced and are in common use in certain localities for evaporating and drying this acetate liquor in automatic apparatus requiring very little labor. The acetate liquor concentrated by some other method to a point very near the separation point is run into a shallow pan in which a steam-heated steel roll revolves, dipping into the concentrated acetate solution for a few inches on its lower surface. A series of scrapers, automatically controlled, scrape the partly dried acetate from the surface of the roll and drop it into the conveyor. The amount of moisture left in the acetate when it is scraped from the roll is regulated by the speed of revolution, by the steam pressure and by the number of times which the surface of the roll is scraped per revolution. Generally the acetate comes from this roll in the form of a thick mud, and this mud is further dried by being picked up on an endless wire belt and squeezed in between the links and between the upper and lower surfaces of the belt. The belt carrying the acetate mud then travels through a drier heated by steam or by some form of waste heat until the acetate is completely dried. It is then automatically removed from the belt by making the belt turn sharp corners to crack the lumps of acetate and by automatic tapping which shakes out the remaining fragments of dried acetate. In this way the acetate liquor is concentrated and dried and the finished acetate of lime dropped onto conveyors and carried to a storage bin without the necessity for any handling.

Destructive Distillation of Sawdust

Many publications on wood-distillation have described in some detail commercial methods for the destructive distillation of sawdust. The Halliday method is the

one most commonly described, and the picture of this apparatus has become familiar. It is, therefore, a fairly common impression that the destructive distillation of sawdust has been in commercial practice for many years. We are certain that until very recently no commercial process of sawdust distillation had ever been in operation in this country, and according to Klar's book published in 1910 no sawdust-distillation process had been in successful operation anywhere up to that time.

There are many difficulties in the way of successful destructive distillation of sawdust. In the first place, wood itself is a good non-conductor of heat and sawdust is even better in this respect, since a mass of sawdust contains many closed air spaces which are still better non-conductors. A stationary mass of sawdust is, therefore, very difficult to distill, since it is almost impossible for the heat required to pass through to the center of the mass. It is necessary, therefore, that the sawdust be stirred either by a rotating retort or by some kind of agitation within the retort. This immediately introduces other complications. Either a stirrer or a rotating retort requires moving parts which must be joined gas-tight to the stationary parts of the retort, and at the temperatures of destructive distillation this is not a simple problem. The agitation of the mass also stirs up a great deal of fine charcoal dust, which tends to be carried out of the retort with the vapors and to clog the condensers. If the process is to be continuous, it is also necessary to introduce the sawdust without introducing too much air and without allowing any of the products of the distillation to escape. The charcoal must also be removed through some kind of a gas-tight seal. The cooling and handling of large quantities of finely divided charcoal is also a problem which has not yet been solved; and this, together with the marketing of large quantities of such a product, again adds to the difficulties of sawdust distillation. Several methods for solving these problems have recently been suggested, and some of them have been carried out in commercial or semi-commercial units.

THE BRIQUETTING PROCESS

The American Wood Reduction Co. avoided many of the problems in connection with sawdust-distillation by making the sawdust into a solid block of wood before distillation. In other words, the sawdust or very small-sized wood was briquetted and distilled in the form of briquets. When sufficient pressure is applied to wood a very solid briquet can be formed without the use of any binding material. These briquets, however, when made of hard wood, tend to fall to pieces during destructive distillation; consequently the benefits of briquetting would be largely lost. It was found, however, that, if these sawdust briquets could be subjected to slight mechanical pressure during the distillation, they remained in one piece and fairly firm, regularly shaped pieces of charcoal could be made by this method.

The process finally developed by this company included the conversion of the waste wood in the form of sawdust or small chips into 4-in. briquets, which were loaded from an automatic loader into retorts, consisting of a series of horizontal tubes 20 ft. long and with an inside diameter slightly greater than that of the briquets. Each of these tubes was provided with a piston, by means of which a small pressure of 8 or 10 lb. per sq.in. could be exerted continuously against the column

ACID LIQUOR EVAPORATORS AND CONTINUOUS METHANOL STILL

of briquets during the distillation. On account of the small diameter of the tubes, each of which really acted as a single retort, the complete distillation could be finished in about three hours, and the temperature control was good enough so that unusually high yields were obtained. The cost of preparing the wood for distillation and the rather complicated and small-capacity apparatus was, therefore, compensated by the high yields and short length of time in the retort. A plant to use this process was under construction for the Bureau of Aircraft Construction during the war, and was about 80 per cent completed at the time of the armistice. This plant was never put into operation, and the process never had a trial on a commercial scale.

THE SAWTELLE PROCESS

The Sawtelle process also avoided some of the usual complications of sawdust-distillation by a combination of the distillation of the wood and the manufacture of producer gas from the charcoal. This was accomplished by using an up-draft gas producer with wood as fuel. The wood in the form of sawdust and fine chips forms a cone-shaped pile in the gas producer, the upper part of which is wood in the drying stage, the next layer wood in the stage of destructive distillation, and the lower layers charcoal in the process of manufacture into producer gas. The heat required for distilling and drying is furnished by the hot gas. Since charcoal is not a product of this process, the difficulties with charcoal dust and with cooling the finely-divided charcoal are not encountered. This process has operated successfully from the mechanical standpoint in a small commercial unit producer, but unfortunately the wood used in these trials was of unknown mixed species, and therefore no comparative figures on the yields of methanol and acid were obtained. There seems to be no reason, however, why this method should not give the maximum yields of both acid and methanol, since the process is a continuous one and the temperature can readily be controlled. In localities where there is a demand for the producer gas obtained, this process should be very promising, but under present conditions the presence of large quantities of hardwood waste in localities where there is also a demand for power is uncommon.

THE STAFFORD PROCESS

This process was developed with the idea of utilizing fully the exothermic reaction of wood-distillation. The process and apparatus is of the simplest, consisting merely of a large, well-insulated chamber into which the dry, warm wood is introduced continuously. The heat of decomposition of the wood is sufficient to bring an equal quantity of dry, warm wood to the distillation point; and the process is, therefore, continuous without the addition of heat from the outside. A thick layer of charcoal is kept in the bottom of the retort and partly cooled charcoal can be withdrawn continuously or at intervals. This process has worked very successfully at small-scale trials, and it is reported that it is now being tried out in a commercial-sized unit. No figures have been given on the yields obtainable by this process, but there seems to be no reason why the maximum yields of methanol and acid should not be obtained.

THE SEAMAN PROCESS

The Seaman process was developed and demonstrated in a commercial-sized unit several years ago. The apparatus consisted of a rotating inclined retort about

30 ft. long by 3 ft. in diameter. The hot, dry sawdust was charged at the upper end and the charcoal was removed continuously from the lower end. The ingenious devices" for introducing the sawdust without introducing air and for removing the charcoal without allowing the escape of gas were found to work very satisfactorily on this demonstration retort. The yield of acetic acid obtained in this apparatus was unusually high, but for some unknown reason the methanol yields were somewhat low. A commercial plant to use this process was ready for operation early in 1918, but many difficulties were encountered, especially the plugging of the condensers by charcoal dust which was carried over from the retorts. It is reported that these difficulties have now been overcome and that several of the retorts are now operating continuously and commercially.

It should be noted here that the problem of sawdust distillation is perhaps not so important as is generally believed. This is for the reason that hardwood sawdust cannot be obtained in quantities sufficient for running a commercial wood-distillation plant without transportation, and sawdust is too cheap and bulky a material to permit profitable transportation for any considerable distance. Therefore, the only sawdust-distillation process which will be of importance commercially is the one which secures such economical operation or such high yields that it can afford to purchase and grind up large pieces of wood to use along with the sawdust.

Removal of Glue Stains*

Casein and vegetable glues containing caustic soda produce stains on certain kinds of wood, notably the oaks, maple, cherry, elm, ash, birch and beech. Some glues stain the wood more than others, and those that contain the most alkali are likely to be most injurious. The staining is due to the action of the alkali in the glue on the tannins and other constituents of the wood, whereby a substance related to ink is formed. No means have yet been found for preventing this chemical action. Precautions can be taken, however, which will keep the discoloration from the finished surfaces.

The most trouble with glue stain in woodworking is caused by the penetration of the glue solution through thin face veneers. This seepage is very likely to occur if the veneer is less than $\frac{1}{16}$ in. thick and somewhat porous. The consistency of a glue in part determines whether it will be squeezed through the wood or not. It is quite obvious that under similar conditions a thin glue will penetrate farther than a thick glue. For this reason the quantity of water that is added to a glue might be diminished and "fillers" added when staining is feared.

If a panel is dried promptly, the caustic soda solution will have difficulty in coming to the surface. Rapid drying can be brought about by removing the panels from the press as soon as it is safe to do so, and placing them on stickers.

Casein and vegetable glue stains can be almost entirely removed by sponging the stained surface with an oxalic acid solution prepared by dissolving an ounce of oxalic acid crystals in about 12 ounces of water. Still better results may sometimes be obtained by moistening the wood first with a sodium sulphite solution made up in the same concentration as the oxalic acid. In this way very stubborn stains can be almost obliterated.

Chemical Control of the Process for De-inking Paper

By C. M. JOYCE

DURING the past fifteen or twenty years, numerous methods for de-inking waste paper have been proposed. Many of these have been tried on a large scale involving great expenditure for equipment and materials. The net result of all this effort, however, may be expressed by saying that most mills are just where they started. The paper maker of today has little faith in new de-inking processes; he is not inclined to spend any time or money trying them. For this reason he is called narrow and unprogressive.

A careful study of the causes of these failures would justify the paper maker in his attitude. Many of those who have proposed de-inking methods have never seen a mill at all, do not have the working knowledge to take account of the interrelations of the market for raw materials and finished paper, cost of chemicals, and special mill conditions. There is no need for extra refinement in de-inking newsprint when the only use for the finished pulp is box board and cardboard filler. There is no use in recommending chemicals worth more than the pulp.

A valuable process for recovering newsprint, discovered by Baskerville and Stevenson,¹ has not received the attention it deserves because it has not provided for the mill difficulties in handling slack sized paper. Mill superintendents immediately raised the question whether newsprint can be used successfully in quantity on account of its rapid absorption of water and tendency to form bunches difficult to disintegrate. A mass of newsprint introduced rapidly into a de-inking bath accumulates near the top, forming an unwieldy wet mass which will often break a paddle before it disintegrates. Without waiting to see how this trouble may be overcome, mill men, with recollections of previous failures, do not care to consider the process. So the old soda boil, followed by washing of the resultant steaming, bad smelling, yellow mass, persists while chemists look on with disgust at the primitive mill methods.

After such a pessimistic beginning, the reader of this paper will not expect a solution of this important problem and the writer will not be sanguine enough even to attempt to propose one. However, a few general principles have been developed out of years of wide effort with small results, and these will be set forth in the hope that they will suggest improvements which some mill men may find adapted to their conditions.

APPARATUS AND TREATMENT

In preparing book stock and newsprint, it is highly desirable to loosen the ink before subjecting the stock to any pulping process which imbeds the ink in the fiber in such a way that its removal is impossible. It is also desirable to use the mildest possible chemical treatment, best accomplished by adjusting the amount of soda ash to a minimum quantity. A temperature somewhat less than boiling is an undoubted advantage as it makes it possible to turn out a pulp less tendered and less yellow.

Had the outside chemist not already discredited himself by proposing chemicals whose price is out of

reason, and apparatus too expensive or unwieldy to handle, he might make a real improvement in the average mill by painstaking adjustment of the factors mentioned.

For the de-inking bath, a boiler can be fitted up for external circulation by connecting it at the bottom to the intake of a rotary pump which discharges tangentially near the top of the boiler. By means of a Y-valve connection, the contents of the boiler can be pumped to the washer when finished. The paper may also be treated with de-inking chemicals in an ordinary beater used with the roll lifted clear of the bed plate (so that the ink will not be ground into the fiber), with a steam supply to raise the temperature of the contents nearly to boiling. If the beater has been used only for cold water previously, the wooden filler between the roll knives should be treated to withstand hot water. For removing the loosened ink a Lancaster washer has been used successfully by many mills.

CHEMICAL CONTROL REQUIRED

The form of apparatus used is less important than the careful chemical control of the process. To obtain the desired quality of product, maximum production and minimum cost of chemicals the following factors must be considered: (1) Ratio of water to weight of paper treated, (2) amount and kind of chemicals used, (3) rate of circulation of alkaline bath, (4) temperature, and (5) time. Increasing proportions of water make the pulp flow more freely so that the ink is more readily loosened by the chemical treatment. The amount is of course limited inasmuch as too large a proportion of water curtails the production. The more freely the pulp flows and the greater the agitation, the smaller the amount of chemicals required, because they will more readily come in contact with the pulp. It is important to have perfect circulation in order to avoid the possibility of a bunch of paper lodging somewhere until the chemical treatment is ended and then becoming free and distributing ink specks throughout the whole mass. Not infrequently excess chemicals are added to overcome defects in reality caused by poor circulation, a practice which adds to the expense and tenders and yellows the fiber. The adjustment of the temperature is also important as too little heat impairs the chemical action and too much heat degrades the fiber. The time of treatment should be determined by taking samples every 15 minutes and washing them on a screen and continuing the treatment until no more ink specks appear.

The success of the chemical control depends on the intelligent co-operation of the chemist with the mill superintendent, a condition which now seems to exist only in the largest mills.

Leominster, Mass.

Paper Manufacture in Japan

The *Japanese-American Commercial Weekly* reports that investigation made by the Association of Japanese Paper Mill Owners shows that the volume of paper manufactured by them during 1920 totaled 565,926,000 lb., an increase of 46,785,000 lb. as against the year 1919.

During 1920, 23,120,000 yen worth of paper was exported and 17,400,000 yen worth was imported, the figures representing a decrease of 2,270,000 yen and 970,000 yen, respectively, as against the preceding year.

The Hardness of Solid Solutions*

In Solid Solutions, Atoms of a Metal Replace Those of the Solute; Solubility Varies Inversely and Gain in Hardness Varies Directly as the Amount of Distortion in the Space Lattice, and Resultant Increase in Internal Energy

BY WALTER ROSENHAIN

National Physical Laboratory, Teddington, England

IT IS a well-known fact of metallurgy that the addition of one metal to another produces an increase of strength and hardness. In some alloys, this change of properties is accompanied by the formation of a new micro-constituent or phase, which is itself harder, and also, as a rule, more brittle than either of the constituent metals. In a very large and important group of alloys, however, the addition of the second metal, up to certain limits of concentration, does not lead to the formation of a second phase or constituent.

STRUCTURE OF SOLID SOLUTIONS

Alloys of this type, when they have attained an equilibrium condition, consist of an aggregate of polyhedral crystals, homogeneous in composition so far as their micro-chemical behavior indicates, and in most respects entirely similar to the constituent crystals of the pure metal, which forms the basis of the alloy. A typical example of this kind is furnished by the alloys of copper with zinc, containing up to about 30 per cent of zinc. Alloys of this type are generally described as "solid solutions," on the ground that the state of intimate mixture which exists in the liquid (molten) solution of the two metals in one another is preserved in these alloys after solidification. In Continental language, such crystals are more frequently termed "mixed crystals" ("Mischkrystalle"), but the present author prefers to avoid this term on account of a possibly misleading interpretation.

A further fact in connection with metallic solid solutions is also well known, but appears to require explanation. A solid solution alloy is always harder and stronger than the pure metal of which it mainly consists, and frequently this difference in physical properties is very marked. Thus, annealed pure copper has a Brinell hardness number of 36, and a tensile strength of about 13 tons per sq.in. An alloy of copper containing 30 per cent of zinc in solid solution, on the other hand, in the corresponding annealed condition, has a Brinell hardness number of 57, and a tensile strength of 20 tons per sq.in. It is the purpose of the present paper to suggest an explanation for this hardening and stiffening effect of the added metal in solid-solution alloys, and to show that this explanation leads to an inference which is in striking accord with well-known facts.

The explanation of the properties of solid-solution alloys which is put forward in the present paper is based upon a conception of the manner in which two metals may crystallize together in the form of solid-solution crystals. As a result of the X-ray analysis of crystal structure, mainly carried out by Sir William H.

Bragg and W. L. Bragg¹ and by A. W. Hull² it is now known that, in a metallic crystal, the atoms of the metal are arranged in certain definite ways on a space-lattice, and that this arrangement may differ in detail from one metal to another, not only in regard to the nature of the lattice (cubical or otherwise) and the occupied points, but also in regard to the normal inter-atomic distance or spacing of the lattice. On the view now put forward, the crystals of a solid solution of metal B in metal A are built up on the same space-lattice as crystals of pure A, the sole difference being that a certain number of individual atoms of A are replaced by atoms of B. It is obvious that the extent to which such an arrangement will be possible must depend upon the relation which exists between the atoms of the two metals. If both tend to take up a similar space-lattice arrangement, and if their normal inter-atomic distances do not differ very much, a single crystal may be built up, upon the normal space-lattice arrangement of A, using atoms of A and B indiscriminately, up to a considerable proportion of B. If the similarity of the two kinds of atom is sufficiently great, then such an indiscriminate construction might easily be conceived as being possible in all proportions between the two kinds of atom. In that case, we should expect to find that the two metals could form homogeneous solid solutions when alloyed in any proportion ranging from pure A to pure B. Such cases are, of course, well known among pairs of very similar metals, such as iron and nickel or silver and gold.

ATOMS OF LIKE SHAPE, FORCES AND NATURE FORM BEST SOLID SOLUTIONS

Where the similarity, in regard to crystalline habit and arrangement, of the two kinds of atom is less complete, it would be anticipated that, up to a certain concentration at either end of the series, the atoms would be built together, indiscriminately upon a single space-lattice, but that, beyond certain limits of concentration, the two kinds of atoms would become segregated into two kinds of different crystals, thus giving rise to a duplex structure of two distinct kinds of crystals, each consisting of saturated solid solution of one metal in the other. The degree of dissimilarity of the two kinds of atom would determine the exact concentration at which this separation occurs, and we would thus expect to find in metallic alloy systems all gradations, ranging from complete mutual "solid" solubility down to almost complete insolubility in the solid state; it is, of course, well known that such gradations are found among known alloys.

From the present point of view, however, interest

¹W. H. and W. L. Bragg, "X-rays and Crystal Structure," p. 173.
²A. W. Hull, "A New Method of Chemical Analysis," *J. Amer. Chem. Soc.*, 1919.

centers on the determining factor which governs the limiting solid solubility of metal B in metal A. If the view of the structure of a solid-solution crystal indicated above is correct, it follows that the actual arrangement of the atoms on the space-lattice typical of metal A cannot exist entirely undisturbed when some of the atoms of A are replaced by atoms of B. The forces acting on any atom of A, for instance, when one of its neighbors in the lattice is an atom of B, cannot possibly be the same as those acting on an atom of A entirely surrounded by atoms of A; there must thus be some want of symmetry in the forces acting on an atom so placed, with a result which is perhaps best expressed by saying that such an atom will be pulled slightly out of its proper place, *i.e.*, that the space-lattice will be slightly distorted at such points. Now, it is evident that such distortion must affect the internal energy of the whole system, and this effect must increase with the increase in the amount of distortion which accompanies the presence of a larger number of atoms of B. A point will therefore be reached when the energy-content of the system as a whole will be less if the atoms of B are separated and arranged on a space-lattice of their own. Such an arrangement implies the existence of boundaries between two different kinds of crystal and the accompanying storage of energy in such boundaries, and it is the balance between the energy-content of the two geometrically possible types of arrangement which must determine the limiting concentration of the solid solution in each case.

POSITION OF DISSOLVED ATOMS IN EQUILIBRIUM

With a full knowledge of the forces at work between adjacent atoms it would be possible to calculate the limiting concentration of any solid solution from the character of the constituent atoms; in the present state of our knowledge, all that can be said is that the greater the extent to which the space-lattice is distorted in the neighborhood of "dissolved" atoms (atoms of "B") the lower will be the limit of solid solubility of B in A. During the process of formation of such a solid solution, a great deal must depend upon the uniformity with which the atoms of B are distributed through the space-lattice. If there is a concentration of the dissolved atoms in any region, then there must be a tendency for rearrangement to occur with a view to arriving at some symmetrical arrangement which shall correspond to the minimum energy-content. If such a distribution is really symmetrical, then an interesting result must follow, *viz.*, that in a solid solution which has been allowed to attain equilibrium conditions, the dissolved atoms will be distributed through the crystals in such a way as themselves to constitute some sort of space-lattice of their own. This is a conclusion which is capable of experimental verification by means of X-ray analysis; when the result is obtained, however, it will be important to realize that the existence of such a secondary space-lattice arrangement of the dissolved atoms (B) does not imply the existence of separate crystals of B. The further question of how far a solid solution which has attained such a state of symmetrical arrangement approaches to the character of a chemical compound need not be discussed here.

The most important conclusion which emerges from what has been said above is that the "solid solubility" of metal B in metal A will be, to a first approximation,

inversely proportional to the amount of distortion of the normal space-lattice of A caused by the substitution of an atom of B for an atom of A in that lattice. The importance of this consideration lies in the fact that this amount of distortion of the space-lattice of A by the presence of B also governs certain of the physical properties of the resulting alloy, particularly the hardness of the material and its resistance to mechanical deformation generally.

HARDNESS IS SLIP RESISTANCE

It is now well recognized that the ductility of metals, *i.e.*, their power of undergoing plastic deformation without rupture, resides in their essentially crystalline character. Plastic deformation takes place within the crystals of metals by a process of slip, occurring on gliding or cleavage planes,³ whereby the crystals accommodate themselves to the new shapes forced upon them by the deformation of the mass. It is precisely the power of the crystals to undergo such slip which governs the ductility of the metal, and their power of resisting slip which determines their power of resisting deformation. If this view is correct, then anything which tends to hinder the free occurrence of slip on the principal planes of a crystal will increase the hardness (or power of resisting deformation) and will lower the ductility of the material. The application of any appreciable amount of plastic deformation (or "cold work") is known to act in this manner, and does so, according to the views of Beilby⁴ by the partial destruction of the crystalline arrangement of the atoms within the crystals.

The view which it is desired to put forward here is that any even slight distortion of the space-lattice of the crystals of a metal by the presence of "dissolved" atoms of another metal, in the manner indicated in the earlier part of this paper, must serve as a hindrance to slip on the crystal planes. Strictly speaking, in fact, the crystal "planes" have ceased to exist in such a slightly-distorted crystal. The very facility for slip which renders metallic crystals soft and ductile depends upon the smooth regularity with which the atoms are arranged on their space-lattice, and if this smoothness is lessened by the slight distortion of the lattice, it is obvious that slip will be rendered more difficult, and this difficulty will increase, to a first approximation, proportionately to the amount of distortion existing in the space-lattice.

HARDNESS GREATEST WITH LIMITING SOLUBILITY

Combining this last inference with the one already drawn above in regard to the factor governing the limiting solid solubility of one metal in another, we arrive at the following conclusion: that since the amount of distortion which the introduction of a given "dissolved" atom produces in the space-lattice of the solvent metal governs both the limiting solubility of the dissolved metal and the degree of hardening produced in the solvent metal, we should expect to find that the hardening effect of one metal upon another in the form of a solid solution should, to a first approximation be inversely proportional to its solid solubility.

This very general conclusion, which—so far as the author is aware—has not been previously stated, ap-

Evaporation by Vapor Compression

BY BURTON DUNGLINSON

EVAPORATION cannot proceed, broadly speaking, unless there is a temperature difference between the heating medium and the liquid being heated. To obtain this temperature difference it is universal practice to employ vacuum systems, which, by reducing the pressure above the liquid, allow ebullition to take place at a lower temperature.

The temperature differences obtained with a triple-effect vacuum evaporator operating at usual vacuum and using exhaust steam at 3 lb. pressure, are shown in the following table:

APPROXIMATE TEMPERATURE DIFFERENCES OBTAINED WITH TRIPLE-EFFECT VACUUM EVAPORATOR

	First Effect	Second Effect	Third Effect
Vacuum (in inches of mercury).....	5	15	28
Pressure of steam (lb. absolute).....	17.7	12	7
Corresponding temperatures, deg. F.....	222	202	177
Boiling point at given vacuum, deg. F.....	180	155	130
Temperature differences, deg. F.....	42	47	47

This demonstrates a maximum temperature difference of 47 deg. F. and an average of about 45 deg. F.

Another way of obtaining this temperature difference is by compressing the evaporated steam and vapors and returning these, either to the heating system of the evaporator or to a second evaporator arranged in series with the first. To obtain a difference of 45 deg. for a solution, which does not increase appreciably in boiling point as concentration proceeds, it will be necessary to compress the evaporated steam to 20 lb. more than its original pressure.

This does not apply to most solutions met with in evaporator practice, since they usually have a considerable elevation of the boiling point before final concentration is reached. This means that, in order to obtain efficient evaporation per sq.ft. of heating surface, very high pressures must be employed, and in fact the compression systems usually require the use of double or triple stage rotary compressors for such industrial operations.

Where it is desired to produce only distilled water or at the most to concentrate a solution to not more than 5 deg. Bé. a simple expedient, which was the forerunner of the vapor-compression systems, has been found readily adaptable to single-effect evaporators.

This apparatus, known as the "Simplex" film evaporator, was developed in London mainly for evaporating sea water. It involves the adaptation of a steam injector to the vapor outlet of the evaporator, the mixed vapor being fed back to the calandria. The efficiency of such steam injectors is extremely low, and only a portion of the evaporated steam can be returned.

Since the whole principle of vapor compression systems depends on low temperature differences, with consequent low compressions, it naturally follows that multiple effects on some such system would have to be used in order to create the desired temperature differences and hence evaporation. Sea water contains about 3 per cent soluble chlorides and when saturated contains about 30 per cent of soluble chlorides. The rise in boiling point in this solution between the concentrations stipulated is about 9 deg. F.

THE SÖDERLUND-BOBERG EVAPORATOR

The Söderlund-Boberg evaporator consists of three elements connected with a multi-stage turbo-compressor. The steam from the evaporating spaces of all of the elements is compressed to a sufficient extent in the

first stage of the compressor for use in the heater of the first element. The excess of steam over that required in the first element is then compressed in the second stage of the compressor to render it fit for the second heater, and the residue from the second heater is then finally compressed in the last stage of the compressor to render it available for the last heater. Each element has its own circulating pump and the hot condensate from the three elements is combined and supplied to a common feed heater.

CONSTRUCTION AND OPERATING DETAILS

A sectional elevation of one element of the evaporator is shown in Fig. 1. The evaporator is comprised of a tall shell A, the greater portion of which is taken up by the calandria B. To the upper end of each tube C is fitted a ferrule (see insert Fig. 1) with a distributing nozzle E. The liquid, which is raised by a pump F from the lower portion G of the shell A, is fed into the tray H

FIG. 1. SECTIONAL ELEVATION OF SINGLE STAGE SÖDERLUND-BOBERG EVAPORATOR

formed at the top of the calandria, and after passing through the nozzle in the ferrules is spread as a thin and rapidly moving film over the inner surface of the tubes C.

The liquid collects again in the bottom of the shell, to which fresh liquid is automatically admitted by the constant level feed I. Thence it is returned by the pump F to the distributing tray H. The steam which is given off by the films inside the tubes and that which is separated from the spray by the baffles J and by the tangential disposition of the steam entry passes to the compressor L. The required quantity of make-up steam is added to it on its way by the pressure-controlled automatic steam inlet M. The compressed steam enters the space around the tubes C and condensing on them is drained off as hot water through the steam trap N connected to a counter-current regenerator or pre-heater O.

The small quantity of non-condensable gases from the feed liquid escapes through the blow-off *Q* or is cleared out of the steam space either by the periodically blowing-off of a little steam or by the continuous emission of a small quantity of steam from this space.

The compressor is driven at a constant speed by a spur gear from a shaft which in turn is belt-driven directly by a gas or oil engine. The exhaust from the engine passes to a small boiler for generating the make-up steam.

CHARACTERISTICS OF FILM EVAPORATION

An important fact in connection with the claims of this system of evaporation is the insistence that a film of the liquid under treatment is circulated down the tubes. Although this is in direct opposition to the direction of flow to be met with in a standard film evaporator, it nevertheless demonstrates the advantages to be gained from the adoption of the film as a means to increased efficiency. An important point which is conceded to the film evaporator is the absence of scaling and incrustation. The writer has found in experiences with various liquids in film evaporators that the high velocities, rapid circulation and continuous motion in an upward direction tend to scour and burnish the tubes rather than to form scale. In this connection the patentees of the Söderlund-Boberg evaporator say: "Film evaporation is, however, notoriously beneficial as regards reduction of scale formation, and experience in climbing film evaporation has shown, what numerous trials with the Söderlund-Boberg evaporator have since confirmed, that the rapid circulation and uniform wetting to which the surface is subjected play an important part in reducing this tendency to within small limits."

MULTIPLE STAGE INSTALLATIONS

The evaporator when used in multiple stage may be considered as a series of units such as have been described. An installation designed for concentrating sea water is shown in Fig. 2. The condensates from the calandria of these units are combined and pass to a single heat regenerator. The concentrate from the bottom of the shell of the one element passes to the next element, and the vapor from all of the elements passes to the common compressor, where its tempera-

ture is raised enough for use in the first calandria. The uncondensed residue of steam then enters into a second compressor or into the second stage of the same compressor and is heated by compression for use in the next calandria.

It is claimed that with this system, producing salt from sea water, there is an evaporative ratio equal to 12 lb. of water per lb. of steam. Such results are truly remarkable and we may look forward to the time when this energy system really proves its value.

Sulphur in Malleable Cast Iron

BY LESTER C. CROME*

IT IS generally known that the evolution method for the determination of sulphur in such materials as white cast irons is not at all reliable. It is also true that the oxidation methods require too much time for advantageous use in a control laboratory. Being confronted with the problem of obtaining a rapid and accurate analysis of white cast irons, a thorough investigation of the problem was made, revealing some very interesting facts and also disproving some popular ideas concerning the determination of sulphur in white irons by the evolution method.

VARIATION BETWEEN EVOLUTION AND OXIDATION METHODS

Complete chemical analyses with duplicate determinations of carbon, evolution sulphur and oxidation sulphur were obtained on forty samples of white iron,

* The carbon and sulphur values were all checked by duplicate determinations.

with the idea that they might reveal some relation existing between the evolution and oxidation values and some third quantity such as the percentage of combined carbon or the carbon:silicon ratio. The results of this investigation listed in Table I showed no such relation—in fact, proved the contrary.

These results classified the samples into three groups as follows:

*Chemist, Dayton Malleable Iron Co., Dayton, Ohio.

FIG. 2. MULTIPLE STAGE INSTALLATION FOR SEA WATER EVAPORATION PLANT

(1) In about 25 per cent of the samples (Nos. 1, 2, 3, 5, 10, 11, 12, 22, 25, 40) the evolution and oxidation values checked.

(2) In another group (Nos. 7, 8, 14, 28, 29, 30, 31, 33, 34, 35, 36, 37, 38) the evolution method gave only about one-half or less of the total sulphur.

(3) The remaining samples gave varying values falling in between these two.

Samples with nearly identical complete analyses could be found in each of the three groups.

MISSING SULPHUR EVOLVED BUT NOT CAUGHT

Samples giving only a small part of their sulphur by the evolution method were studied more thoroughly to determine what became of the missing sulphur. Accordingly several of them were picked and 10-g. samples treated with hydrochloric acid exactly as in the ordinary evolution method. After the samples had dissolved, their solutions were filtered. The filtrates were oxidized with bromine, evaporated with nitric acid after the addition of sodium carbonate and examined for sulphur according to the regular oxidation procedure. The results of this experiment showed that the solutions contained no sulphur whatever. The residues were carefully dried at 100 deg. C. and tested for sulphur by using both the nitric acid solution method, that of the U. S. Bureau of Standards, and by fusing with a potassium nitrate and sodium carbonate mixture. These results showed that only traces of sulphur remained in the residues.

From the results of these experiments, listed in Table II, it was evident that the sulphur not obtained by the

TABLE II. EXAMINATION FOR MISSING SULPHUR

No.	Sulphur by		Sulphur in	
	Evolution	Oxidation	Residue	Filtrate

evolution method must be evolved as some sort of a gaseous compound which is not absorbed by the ordinary media.

SULPHUR LOST ON ANNEALING

There is a popular idea that by annealing a cast iron it will give its total sulphur by the evolution method, even though it did not do so before. Accordingly two test-bars of the class where only half of the sulphur was evolved were placed in an electric muffle at 1,800 deg. F. and allowed to cool very slowly with the furnace. Then the sulphur was determined on these samples by both the evolution and oxidation methods. The results of both methods checked very closely, but instead of agreeing with the original oxidation value, they checked that of the evolution value before annealing. An amount of sulphur equal to the difference between the two had been lost.

This proved to be very interesting.

Then five typical samples were selected from each group, and bars from these heats that had been through the annealing process in the regular annealing ovens (carbon completely graphitized) were obtained and their sulphur was determined by both the evolution and oxidation methods. These results, in Table III, substantiated those of the preliminary experiment, showing that the sulphur not obtained by the evolution method in the white iron was lost in the annealing process. In

all cases the sulphur values of both methods checked on the annealed samples, but in some cases they were slightly higher than the original evolution value, due to the small amount of sulphur which is usually taken up in the annealing oven.

These results show that in cases where the total sulphur in the white iron is not obtained by the evolution method it must be present in two distinct forms. That which is obtained is doubtless in the form of manganese and ferrous sulphides, and the remainder must be in some other form, but just what it might be the results obtained thus far do not show.

TABLE III. SULPHUR VALUES ON REGULAR ANNEALED SAMPLES

19	0.053	0.073	0.063	0.060
20	0.047	0.077	0.064	0.060

There is one point practically certain, however: no matter in what form this sulphur does exist, it does not have the same deleterious effects on the iron as the ordinary sulphur as sulphides. This, however, is only as might be expected from the fact that this amount of sulphur is subsequently lost in the annealing process.

In view of this fact, it is possible to determine the sulphur in white cast irons by the evolution process, for even though it does not give the total sulphur in all cases, it always gives that which is injurious, and that is all that is desired to know in the control laboratory routine.

An Extensometer Calibrating Device

BY R. L. TEMPLIN*

MOST of the extensometers made in this country and used by the various industrial and technical school materials laboratories are purchased and accepted from the maker as being correct. The instrument will generally measure correctly when received, although this is not always the case, but even the best extensometers will not continue to measure correctly after considerable usage. In general, an extensometer indicating to the nearest 0.0001 in. is sufficiently accurate for the ordinary testing of materials in which it is desired to determine the proportional limit, elastic limit, yield point and modulus of elasticity. This is the accuracy required by the standards of the American Society for Testing Materials.

It is one thing to have an extensometer indicating to the nearest 0.0001 in., and quite another to have the instrument measure correctly to the nearest 0.0001 in. within, say ± 0.00002 in. Very few industrial or technical school laboratories are equipped to calibrate an extensometer, or if so equipped the calibration devices are so cumbersome that they are seldom used. By means of the rather simple device described in this article, it is possible to check the various types of com-

*Chief Engineer of Tests, Aluminum Co. of America.

mercial extensometers with a degree of accuracy sufficient for ordinary testing.

Since most commercial-type extensometers have some system of multiplying levers in order to magnify the

0.001 in. we will find that the error in the calibration device micrometer becomes the small part of the indicated error of the extensometer. Attacking the problem of calibration from this angle makes it unnecessary to have the calibration device read correctly to 0.00001 in. It has been found sufficient for practical use to have the calibration device indicate only to the nearest 0.0001 in.

DESCRIPTION OF INSTRUMENT

The calibrating device consists essentially of a steel tube in the upper end of which is fastened a standard micrometer head, indicating to the nearest 0.0001 in. and in the other end of which a rod slides so as to form a telescoping bar (see Fig. 1). The lower end of this rod is fastened into a suitable stand or base. It is hardly necessary to state that the bar must have an accurate fit in the tube. Also the small adjustable key which keeps the tube from rotating on the bar must be well fitted.

In order to provide a suitable bearing for the end of the micrometer screw, a steel ball is placed in the center of the bar. While this ball does not rotate during the operation of the instrument, it nevertheless affords an inexpensive and quite suitable bearing.

The weights attached to the cross-arm at the top of the tube are provided in order to make the action of the instrument positive at all times. They should weigh from 1 to 2 lb. each. The weights are attached rigidly to the arm at such a distance from the tube as not to interfere with the operation of any extensometer likely to be calibrated. The micrometer head is held in place by a clamp which is made as part of the weight arm.

The shoulder near the middle of the bar acts as a stop for the tube when the micrometer head is removed or the micrometer screw removed for adjustment. The bar and tube should have an outside diameter of $\frac{1}{2}$ in. in order to accommodate the different extensometers on the market, which are intended for use only on the standard 0.505 in. diameter test specimen. It is advisable to have punch marks or small drilled holes (No. 56 drill) on opposite sides of the bar and tube, 1 in. and 4 in. above and below the shoulder of the bar.

The accuracy of the instrument is, of course, based

FIG. 1. SIDE VIEW AND CROSS-SECTION OF CALIBRATING DEVICE

strains whose magnitudes are to be measured, advantage is taken of this magnification in their calibration. Any error caused by an error in the length of one or all of the levers in an extensometer is multiplied considerably if the extensometer is made to function throughout its whole range of measurement. For example, the observed differences in the readings of the extensometer and calibration device throughout the range of deformation of 0 in. to 0.001 in. may be so small as to be directly comparable to the error of the calibration device micrometer, but if we extend the range of the calibration curve to ten or twenty times

FIGS. 2 TO 4. VARIOUS EXTENSOMETERS ARRANGED FOR CALIBRATION

Fig. 2. 2-in. Riehle extensometer. Fig. 3. 2-in. Ewing extensometer. Fig. 4. 2-in. Berry strain-gage.

upon the accuracy of the micrometer head, and for this reason the micrometer head which has been selected for the instrument should be calibrated. The U. S. Bureau of Standards is equipped for doing this at a nominal charge.

Some extensometers, because of their inherent design, will indicate strains accurately in but one direction. This is a common fault with instruments having indicating dials due to back-lash in the gear trains of the dials. The calibrating device will operate positively in either direction, so it is very well suited for checking up extensometers of this type.

METHOD OF PROCEDURE

In operation, the extensometer is attached to the instrument as shown in Figs. 2, 3 and 4. Care should be used not to clamp the extensometer too tightly on the tube, else the tube will be deformed enough to keep it from sliding freely on the bar. Since the extensometer readings are to be referred to the readings of the increments of the calibrating device, the extensometer is usually set at some even figure or preferably zero. If the extensometer has a zero adjustment, it

FIG. 5. CALIBRATION CURVE OF A 2-IN. RIEHLÉ EXTENSOMETER

saves considerable computation work to set the extensometer at zero simultaneously with the setting of the calibrating device. The micrometer screw is then turned a predetermined increment, 0.001 in. or 0.002 in., a reading of the extensometer noted, the micrometer screw turned the same additional increment and the extensometer reading again noted. This procedure is followed throughout the range of the extensometer. The data obtained are then plotted using the micrometer readings as ordinates and the corresponding extensometer readings as abscissæ. The scale used in plotting the data should best be selected so that the scale for the abscissæ or extensometer readings is as many times as large as the ordinate scale as the lever multiplication ratio of the extensometer. This will make the resultant curve have an angle of 45 deg. with the X- and Y-axes, if the extensometer is correct.

A sample calibration is shown in Fig. 5. This curve was drawn from data obtained in the calibration of a Riehle extensometer, using a 2-in. gage length. (See Table I.) Referring to the diagram, it is seen that the calibration curve A crosses the 45 deg. line. This indicates that the zero setting of the extensometer was at fault. By drawing a second line B, parallel to A and

TABLE I. CALIBRATION TEST DATA OF 2-INCH RIEHLE EXTENSOMETER

Micrometer Reading	Micrometer Difference	Dial Reading	Error

0.696	0.036	0.01825	+0.00025
0.694	0.038	0.01922	+0.00022
0.692	0.040	0.02018	+0.00018

passing through the origin, we get the true error of the extensometer. This curve shows that the extensometer gives measurements which are 2 per cent too large. To correct this error, it would be necessary to shorten one of the levers of the extensometer by 2 per cent.

If the multiplying ratio of the extensometer being calibrated is not correct, and the scale, dial or micrometer screw of the extensometer is correct, the resultant curve will be a straight line but will not make an angle of 45 deg. with the axis. In such a case a way can usually be found for changing the multiplication ratio of the extensometer.

By observation of the calibration curve it is easy to see whether the multiplying ratio should be increased or decreased. If the observed readings cause the curve to make an angle greater than 45 deg. with the X-axis, the multiplying ratio should be increased; if less than 45 deg., the ratio should be decreased. After making a slight *known* change in the ratio, usually by increasing or decreasing the length of one of the levers, a second calibration of the instrument is made. From the two calibrations and the known amount of alteration in the levers it is comparatively easy to make a second definite change in the levers which will cause the instrument to read correctly. The instrument, however, should be checked with another calibration after the final adjustments are made.

When the calibration curve is not a straight line, it is due to (1) careless setting of the micrometer of the calibration device, (2) inaccuracy of the micrometer screw of the extensometer or of the dial of the extensometer (generally because of the eccentricity of the gears in the dial), or (3) to a combination of these causes. In any case the calibration should be repeated using care to see that the micrometer of the calibration device is accurately set. A small hand magnifying glass will be found useful in setting the micrometer head. If after these precautions have been taken and it is still found that the calibration curve is not a straight line, and that the discrepancy between the curve and the 45-deg. line is considerable, then account of this discrepancy will have to be taken in the data obtained in the use of the extensometer, or a new micrometer screw or an accurate indicating dial or scale will have to be provided for the extensometer.

It has been the experience of the writer that it is usually best to check all the lever motions and working joints of an extensometer before using the instrument in order to make sure that they work easily

without lost motion. Where the extensometer is provided with a micrometer screw for checking or calibration purposes, as in the case of the Ewing extensometer, the reading of this micrometer screw is used as an additional check on the reading of both the extensometer scale and the micrometer of the calibration device. Ten readings are usually considered sufficient for a single calibration.

New Kensington, Pa.

Local Heating With a "Pyrotip"*

In practically every line of manufacture some means of local heating is required for various operations. The most common form is the gas flame, using illuminating gas with or without compressed air. In fine work, as in jeweler shops, the alcohol lamp and blow torch are used. For portable work the gasoline blow torch is commonly used. For more intense heat the oxy-acetylene flame is employed, as well as the electric arc, using either carbon or metallic electrodes.

A convenient and economical method of local heating is obtained by using the Pyrotip, which is the trade name given to a low voltage transformer that has been specially designed for work of this nature. The secondary of the transformer furnishes sufficient current to quickly heat up the point of an ordinary $\frac{3}{8}$ -in. carbon rod. The voltage is so low that an arc cannot

be drawn, but the temperature of the carbon point can be varied through a wide range by simply altering the amount of contact surface at the end of the carbon.

by conduction. The transformer can easily be used to heat soldering coppers by attaching a suitable holder to the low-tension terminals, and with advantage, since there is no danger of superheating and burning the end.

In jewelry stores a considerable amount of silver soldering is required in repairing broken silver spoons, gold rings, etc. The Pyrotip, utilizing a split or forked carbon electrode, is readily used. In this same line of work they have frequent need to melt down pieces of gold, silver, or platinum. The platinum works down in relatively small quantities, and it only takes a few seconds to melt down the platinum, whereas the gas ordinarily available requires a considerable length of time. It is also a simple proposition to utilize the same combination to melt down pieces of gold or silver from watch cases, putting them in small ingot form.

In the same way dentists can utilize the device for melting down old gold fillings, bringing them back to shape so that they can be used over again.

Dark glasses are desirable in this work, although not so essential as with other forms of local heating, due to the ease with which the eyes can be protected by properly manipulating the holder.

PYROTIP, FOR LOCAL APPLICATION OF HIGH TEMPERATURES

be drawn, but the temperature of the carbon point can be varied through a wide range by simply altering the amount of contact surface at the end of the carbon.

The most evident field for this device is in the melting or joining of lead parts or terminals of storage batteries. Lead, unless a clean surface is obtained, cannot be readily melted with a soldering copper. Temperature control, especially for lead burning, is accomplished by altering the depth of submersion of the carbon tip in the molten lead. That portion of the carbon which is submerged assumes a temperature but little above the melting point of lead, 326 deg. C. Just above the surface the carbon is much hotter, approaching 1,200 deg. C. when submergence is $\frac{1}{8}$ in., and 700 deg. when immersed $\frac{1}{2}$ in. The greater energy put into the lead under these conditions is dissipated without leaving a high temperature because of the greater contact surface between the carbon and the lead. It permits the lead to carry off the heat and radiate it more rapidly.

In direct soldering, the hot point of the carbon burns the tin in the solder; so successful work involves "tin-ning" the surfaces by other means, and then placing the hot point somewhat back from the joint and heating

Recent Chemical & Metallurgical Patents

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Heat-Treatment of Rubber.—In the heat-treatment of rubber for reforming or vulcanizing, a solution is employed having its boiling point at or slightly above the temperature required, the solution being at or slightly below boiling point. Solutions of calcium chloride of various strengths are preferred, the boiling points of which rise approximately 10 deg. F. for every half-pound of salt to $1\frac{1}{2}$ pints of water. Several forms of apparatus are described. Articles or molds containing them may be immersed directly in the liquid, or placed in a jacketed vessel, the jacket of which contains the solution directly heated or circulated from an outside heater. Hollow bodies may have the hot solution pumped into their interiors. (Br. Pat. 161,648; H. GARE, Hazel Grove, Stockport, Cheshire. June 8, 1921.)

Recovering Tin From Scrap.—Tin scrap is treated with oleum to dissolve the tin, and the material is then lifted out of the acid and washed in water. Fresh acid is added to replace that used, and another batch is treated. After a time a basic sulphate SnSO_4 , SnO_2 deposits and is drawn off. The washing water contains some insoluble oxide, SnO_2 , and some tin in solution. The dissolved tin is recovered by precipitation as sulphide or iron is added to neutralize the acid and obtain metallic tin. External heat is not required in the process, but the acid bath is maintained by the exothermic heat and the periodical additions of fresh acid at a fairly constant temperature of 45-55 deg. C. and a strength of about 10 per cent free sulphur trioxide. (Br. Pat. 161,654; P. A. MACKAY, London. June 8, 1921.)

Pure Copper Sulphate.—Pure copper is dissolved in sulphuric acid or oleum in the presence of a soluble compound of a metal electro-negative to copper such as silver or mercury, or selenium. The electro-negative element may be added to the acid and then a solvent for it, such as nitric acid for silver or mercury. When blister copper is employed as raw material, one of its impurities may be used as catalyst, the necessary solvent, say nitric acid for silver or hydrochloric acid for selenium, being added. If an excess of copper is employed, the electro-negative metal used and any gold or silver in the copper are deposited on the excess

*From an article by E. A. Wagner in the *General Electric Review*, vol. 24, p. 628 (July, 1921).

copper and may be recovered. The process may be employed for refining copper. (Br. Pat. 161,656; P. A. MAC-KAY, London. June 8, 1921.)

Preparation of Oxyaldehydes.—Oxyaldehydes are prepared by the interaction of phenols or their derivatives with formaldehyde in the presence of a nitroso compound and a condensing agent. Preparation of vanillin by treating guaiacol and formaldehyde with *p*-nitrosodimethylaniline is described. Nitroso compounds specified are nitrosobenzene, nitrosonaphthalene, and *p*-nitrosodimethylaniline, hydrochloric acid being mentioned as condensing agent. (Br. Pat. 161,679; SOC. CHIMIQUE DES USINES DU RHONE, Paris. June 8, 1921.)

Organo-Mercuric Compounds.—Water-soluble derivatives of salicylic acid containing nuclear mercury are obtained by treating hydroxy-mercuric-salicylic acid anhydride or the like with a soluble cyanide at moderate temperatures and separating by fractional crystallization the resulting *o* and *p* compounds of the formula $\text{NC.Hg.C}_6\text{H}_3\text{OH.COOR}$, where R may be potassium. The reaction may be effected with cooling and in the presence of such quantity of water that both salts are separated, the liquid being iced before filtering. The product may be washed on the filter successively with ice water, 50 per cent alcohol, and concentrated alcohol, and lixiviated with three times its weight of water at 25 deg. C., to extract the more soluble *p*-compound, the residual *o*-compound being then recrystallized from hot water. Alternatively, the reaction may be effected in the presence of more water at ordinary temperatures; after heating, the *p*-compound is found in the solution and the *o*-compound remains undissolved. By adding acids to the aqueous solutions of the potassium salts the free acids may be precipitated. The silver salts may be prepared by adding silver nitrate. The potassium salts are suitable for therapeutic use. (Br. Pat. 161,922; not yet accepted; J. D. RIEDEL AKT. GES., Berlin. June 8, 1921.)

Treating Lead Zinc Ores.—Argentiferous lead-zinc sulphide ores are roasted with a halogen salt such as sodium, potassium, calcium or magnesium chloride in an oxidizing atmosphere at a temperature above 400 deg. C. but not high enough to volatilize lead chloride, the zinc sulphide remaining for the most part unattacked. To prevent any appreciable attack on the zinc the temperature should not exceed 500 deg. C. The air employed in the roasting is preferably moistened if dry. The product of the roasting is leached with hot brine to extract lead, some silver and any zinc chloride. The lead and silver are recovered in known manner—for instance, by cooling the solution and treating the deposited chlorides to separate the silver as argentiferous lead sulphate, the brine being used repeatedly. The residual ore is treated with a solvent for silver such as a solution containing 35 per cent calcium chloride and 3 to 5 per cent cupric chloride or 3 per cent hydrochloric acid or, if there is appreciable quantity of lead, the ore is first treated with hot brine containing hydrochloric or sulphuric acid to extract the lead. The used brine containing sodium sulphate and the lead salts obtained may be treated to desulphate the brine and obtain lead sulphate. In a modification, if there is some unoxidized lead sulphide remaining after the roasting or after the leaching with brine, the ore is leached with hot strong solution of calcium or magnesium chloride containing enough hydrochloric acid to convert the lead sulphide into chloride. This effects a good extraction of the silver and renders a subsequent extraction unnecessary. It is preferred to have a small quantity of zinc chloride present in the calcination, which may be derived from the ore if it contains some easily attackable zinc or may be added at the beginning or toward the end of the calcination, preferably as a mixture of sodium and zinc chlorides obtained by evaporating some of the brine used for leaching. (Br. Pat. 162,026; F. E. ELMORE, Boxmoor, Hertfordshire. June 15, 1921.)

Purifying Zinc Solutions.—A zinc-sulphate or other zinc solution is freed from foreign metals by treatment in the presence of a mercury salt with a subdivided metal electro-positive to the impurities. Zinc, aluminum and alloys thereof are suitable electro-positive metals; they may be powdered or granulated, zinc fume or blue powder being

advantageous. The mercury as mercuric chloride or nitrate, or, when zinc is to be electro-deposited, as mercuric sulphate, may be added as a solution or directly dissolved in the zinc solution before the treatment or at any suitable prior stage. Two pounds of mercury in the form of sulphate, and 40 lb. of zinc, suffice for 10 tons of crude zinc solution. This may be obtained from ore by treatment with spent electrolyte or other solution, and before the purification is brought to an acidity of 0.1 to 0.2 per cent, by means of incomplete neutralization, or by neutralization for the removal of silica, etc., followed by acidification. During the purification the liquid may be heated to 70-100 deg. C. and gently agitated. Copper, arsenic, antimony, bismuth, cadmium, nickel, cobalt and other metals are precipitated as a sludge, from which mercury can be recovered by distillation or otherwise. Iron may be removed before or after the above purification. If aluminum is used as the electro-positive metal, it may be subsequently removed, but is not injurious in the electro-deposition of zinc. (Br. Pat. 162,030; S. FIELD and METALS EXTRACTION CORPORATION, both in London; June 15, 1921.)

Spongy India Rubber.—In the manufacture of porous expanded india rubber by vulcanization in an inert gas under high pressure, a wax or resinous substance, such as ceresin, is added to the ingredients to minimize the diffusion of gas from the spongy mass. The wax or resin may be omitted from the outer layer, which then gradually loses its gas and forms a resilient skin which prevents excessive expansion of the interior mass. The ingredients are

placed in a shell 1 surrounded by an outer vessel 8, which is provided with a heating-jacket 15. Compressed gas is admitted to the vessel 8, and when a certain pressure is attained adjustable automatic valves in the passages 6 admit the gas to the inner shell. Heat is then applied, and temperature and pressure are gradually increased to the maximum values of about 305 deg. F. and 75 atmospheres. When vulcanization is complete, the temperature is first somewhat reduced and then the vessel 8 is rapidly exhausted. The automatic valves at 6 retain a pressure of about 100 lb. per sq.in. in the shell 1, which is allowed to remain until the product has cooled and is then released. A mixture of rubber and balata may be substituted for pure rubber if desired, but the proportion of rubber should not be less than one-third. (Br. Pat. 162,176; C. L. MARSHALL, Harlesden, London; June 15, 1921.)

Analyzing Gases.—Apparatus for carrying out two series of analyses is so arranged that in both series at least one constituent of the gas is always included; for example, in one series the percentage of carbon dioxide is determined,

and in the other series the total percentage of carbon dioxide, carbonic oxide, hydrocarbon and hydrogen. The two series of analyses may be recorded on a common diagram, the recording device being so constructed that alternate lines correspond to the two series of determinations. As shown, the first measuring-vessel *d* is connected to an oscillating vessel *g* containing liquid and which according to the position of the vessel seals one or other of the pipes

h, i; the sample therefore passes alternately to the absorber *k* when the percentage of carbon dioxide is to be determined, and to the oxidizing furnace *l* and then to the absorber *k* for recording the percentage of carbon dioxide, carbonic oxide, hydrocarbon and hydrogen. (Br. Pat. 162,249, not yet accepted; SVENSKA AKTIEBOLAGET MONO., Stockholm; June 15, 1921.)

Important Papers to Be Presented at the Seventh National Exposition of Chemical Industries

At the Seventh National Exposition of Chemical Industries, which will be held during the week of Sept. 12, 1921, in the Eighth Coast Artillery Armory, New York City, important papers will be presented on: Crushing, Grinding and Pulverizing; Evaporating and Drying; Power Plants in the Chemical Industries; Paints and Varnishes, and Industrial Problems. There will also be shown a series of motion pictures on subjects related to chemical and mining industries, handling of materials, and power plants.

The papers to be presented, according to the tentative program, are:

Senate Committee Busy on Tariff Bill

The greatest uncertainty prevails, as this is written, as to what the Finance Committee of the Senate may do in regard to protection for the dye industry. It is recognized by all who are following the matter closely that the committee is almost evenly divided on the subject. The most determined efforts have been made to convince the committee that the limited embargo plan is absolutely necessary to the maintenance and growth of this new American industry. On the other hand, the opposition has been equally energetic in the presentation of its contentions. It is admitted by each group that the action of the committee is anyone's guess.

Almost the same situation exists with regard to American valuations. In regard to that portion of the tariff bill, however, there seem to be more who believe that the committee will reject the scheme as it is carried in the House bill, with the probability that the committee will favor the Davis modification. During the hearings the committee seems to have been impressed by the arguments that the American valuation plan as passed by the House will be impracticable of administration in its application to many commodities, and that it will lay an intolerable burden on the appraiser. The committee also seemed to be impressed adversely by the prospect of price pyramiding in certain commodities. On the other hand, the committee has a thorough understanding of the difficulties and inequities certain to come from foreign valuations under existing conditions.

COMMITTEE INSISTS ON FACTS

An idea of the rather grueling character of cross-examination to which some of the witnesses before the Finance Committee were subjected may be obtained from the following extract from the stenographic report of the testimony of Henry Howard:

Senator REED. Do you believe that an article that can be sold abroad in competition with the world needs protection in America against foreign products?

Mr. HOWARD. I can imagine that there would be cases where it would need it.

Senator REED. Why?

Mr. HOWARD. To prevent dumping over here.

Senator REED. That is the only thing you can think of?

Mr. HOWARD. To prevent methods of unfair competition.

Senator REED. But if unfair competition could be employed in our markets, it could be employed against us abroad at the same time, could it not?

Mr. HOWARD. It could, but might not be.

Senator REED. You really want it so that the American manufacturer can sell in America on a high level and then dump his surplus in Europe?

Mr. HOWARD. I think that is probably a desirable thing to have.

Senator REED. Undoubtedly. I thought so.

Mr. HOWARD. And I think that it is the way it is generally tried to carry it out abroad, also.

Senator REED. That is to say, the American people must have a tax levied upon everything that we consume in order that the manufacturer can sell to them at a high price and sell abroad at a low price.

Mr. HOWARD. These conditions carried out to a reasonable extent make for the prosperity of the American people by enabling us to pay high wages.

Senator REED. And, carried out to a reasonable extent, you mean carried out far enough so that the American manufacturer makes a good fat profit here—

Mr. HOWARD. Makes a fair profit. Internal competition will prevent his making too big a profit.

According to some of the members of the committee, the arguments for or against duties have been composed too greatly of generalities. Senator Reed believes that industries asking for protection should submit statements showing the wage rate to both skilled and unskilled labor; statements as to gross profits, net profits, dividends, surplus, amounts of excess profits and other data, which would make the determination of tariff rates more intelligent.

TESTIMONY OF CHEMICAL MANUFACTURERS

A. G. Rosengarten, of Philadelphia, appeared before the committee to request a compensatory duty on mercurial preparations, since the House of Representatives increased the rate on quicksilver from 7c. to 35c. per lb. He suggested that the compensating duty on calomel, corrosive sublimate and other mercurial preparations should be 25 per cent ad valorem and 32c. per lb. Mr. Rosengarten also protested against the duty of 7c. per lb. placed on citrate of lime by the House. He pointed out that this is the crude material for the manufacture of citric acid on which a duty of 12c. per lb. was placed. Mr. Rosengarten argued that should those duties become effective, the Eastern manufacturers of citric acid would be compelled to close their works. Since 2 lb. of citrate of lime is required to make 1 lb. of citric acid, it would mean that the duty on the finished product is lower than the duty on the crude material. He suggested that not more than 2c. per lb. should be imposed on citrate of lime.

Frank Kidde, secretary of the Monmouth Chemical Co., protested against the proposed duty of 1c. per lb. and 15 per cent ad valorem on chlorate of potash. To have an ad valorem tariff on an American valuation basis, he said, would mean that the valuation would be based on a market value established by a single manufacturing group, which practically controls the manufacture of chlorate of potash in this country.

Dr. Max Mueller, of New York, asked that the photographic chemicals rhodal and metol be given rates of 30 per cent ad valorem and \$1.50 per lb. and 30 per cent ad valorem and 50c. per lb., respectively. These rates are necessary to protect two of the most widely used chemicals in the developing of photographic films, he stated.

Dr. Frederick W. Russe, of St. Louis, stated that 10c. per lb. is insufficient to protect the manufacture of medicinal tannic acid, and he asked for increased duty and a change in the method of classification.

A. S. Somers, representing the Association of Dry Color Manufacturers, pointed out the need for supplying specific duties for all colors and pigments derived from coal-tar products. He also called attention to compensatory duties which should be provided as a result of the increase in the rate of duty on quicksilver.

CANADIANS PROTEST

A very complete presentation was made by those interested in the chemical products made at Shawinigan Falls, in Canada. To enable Canadian industry to continue to purchase raw materials in the American market, Canadian finished materials cannot be barred entirely from the United States, it was argued. It was declared that Canadian glacial acetic acid is essential to the American dye and other

chemical industries if they are to compete in export markets. There are no producers of synthetic acetic acid in the United States, it was declared, nor is there any immediate prospect of this product being produced from acetylene gas synthetically, as now is being done in Canada. Glacial acetic acid, it was contended, should be left on the free list. To impose the 2c. per lb. provided by the House bill would penalize the American consumer, it was said, and place American dye and chemical industries at a distinct disadvantage in meeting competition abroad.

Ellwood B. Speare, representing the Goodyear Rubber Co., revealed that acetaldehyde and paraldehyde are being used with great promise in increasing the rate of vulcanization and for giving better quality to rubber. The use of these materials, he explained, is still in an experimental stage, and unless they can be obtained without payment of an excessive rate of duty he believes their use would have to be discontinued.

The Shawinigan industries also protested against a duty of 1c. per lb. on carbide. It was held that this rate is prohibitive. It would be impossible to ship to the United States if a duty of \$20 per ton were levied. It was stated that the item would yield no revenue and that it simply would have the effect of increasing the business of the Union Carbide Co. by about 15,000 tons annually.

Dr. H. C. Wright, representing the Manufacturers' Association, argued against any embargo privileges for aromatic chemical products in that the question of quality is paramount. It is absolutely essential to successful competition, he declared, to have the very finest products. He also stated that very few of the aromatic chemical products listed in the bill are produced in America equal in quality to the foreign product.

J. D. C. Bradley, of the American Agricultural Chemical Co., opposed the duty on potash. Among other things, he said:

I do not believe that this country can successfully compete with German or French potash unless actual deposits of potash salts are discovered. The potash produced from the Nebraska lakes is low grade and inferior in quality to the German article either for direct application or for use in mixed fertilizers. The California product contains a certain amount of borax, which is deleterious to plant life, and this company is unwilling to risk its use. Other companies who have used it have suffered heavy losses in consequence of the borax injuring the crops. It is now claimed that the amount of borax has been reduced to a safe percentage, but of this fact we are not as yet sufficiently convinced to risk using it in our fertilizers.

I cannot believe that Congress will consent to levy a tax upon the products of the soil and indirectly upon the very sustenance of every citizen.

DYE EMBARGO ESSENTIAL TO NATIONAL DEFENSE

Chemical warfare is not likely to be restricted, even if limitation of armament should be agreed upon, in the opinion of General A. A. Fries, the head of the Chemical Warfare Service. He expressed this belief to the Finance Committee of the Senate in response to an inquiry by Senator Penrose, the committee chairman. General Fries was called before the committee to testify as to the national defense feature of the dye embargo. He contended that such an embargo is absolutely essential to the development of materials necessary to the national defense.

In expressing the conviction that there would be no restriction placed on chemical warfare by any disarmament limitation agreement, General Fries, among other things, said:

"Chemical preparedness is the only means of national protection which can be developed and maintained in times of peace without cost to the country. The disarmament conference may result in restricting the construction of battleships and big guns, since that would reflect large economies for all the nations concerned, but for the United States to cease to prepare for the manufacture of war gases would put us at the mercy of an outlaw nation."

DYE CONSUMERS PRESENT VIEWS

Not all consumers of dyes are opposed to the embargo plan. Daniel F. Waters, Philadelphia, was among those who urged its adoption. He stated that American makers

are perfecting their processes, are reducing their prices and will soon be in a position to give entire satisfaction. Practically all of the consumers of dyes, however, opposed the plan, largely on the ground that it is impossible to get the necessary quality in most dyes of American manufacture. It was admitted that a few American dyes equal the German product, but that the great majority of the colors are not fast. Alfred A. Hodshon, a manufacturer of felt hats, declared that it had been necessary for his company to revolutionize its manufacturing methods so that hats could be dyed after they are molded. When German dyes were available, the dyeing was done before the molding process. He declared that American-made colors will not hold throughout the manufacturing process.

The committee apparently was impressed more by the testimony showing the delays and difficulties of securing importations, or even rulings, through the War Trade Board procedure, than it was by the statements as to lack of quality. The committee seems confident that American manufacturers will be able to attain the necessary quality standards, but very evidently is extremely dubious as to the practicability of any such administration as it is proposed to vest in the United States Tariff Commission.

Chemical Exposition Notes

MINERALS, METALS AND ALLOYS

To the user of minerals and metals the Seventh National Exposition of Chemical Industries, which will be held in the Eighth Coast Artillery Armory, New York, Sept. 12 to 17, offers exceptional possibilities for actual investigation, study, technical information and advice, whether it be a new alloy or the more precious metals.

There is, for instance, an alloy discovered in 1905. The average brass foundryman, after finding out that the metal had a fair percentage of copper, decided that it ought to be a simple proposition and proceeded to cast it in the same manner as he would brass. As a matter of fact it is difficult to cast. It is much more sensitive to oxidation, has a higher shrinkage, and demands a much larger percentage of metal in the gates and risers. It must be kept carefully covered and must be deoxidized before pouring. These difficulties are gradually being overcome, through the education of the foundrymen, especially through a plant service station where foundrymen can go for advice and information, where they may familiarize themselves with the use of the metal.

This particular metal is non-corrodible, strong as steel, tough and ductile. It can be machined, forged, soldered and welded both electrically and by the oxy-acetylene process.

There are many cases where ignorance of the best methods to employ in working with individual alloys or minerals with peculiar properties has prevented the best results or advantages to be obtained with these metals.

There will be a splendid exhibit of minerals, metals and alloys at the exposition, where the highest knowledge and experience of the chemical world will be at the command of any investigator.

Acting Chief Named for Bureau of Chemistry

Expecting that some time yet may elapse before the new chief of the Bureau of Chemistry will be selected, the Secretary of Agriculture has designated Walter G. Campbell as the acting chief of that important bureau of the Department of Agriculture. Dr. W. W. Skinner was designated at the same time to be assistant chief.

Mr. Campbell has been with the Bureau of Chemistry since 1907. He helped to organize the inspection work under the food and drugs act. In 1916 he was made assistant chief in charge of the enforcement of the food and drug regulations. He is a native of Kentucky and a graduate of the University of Kentucky.

Dr. Skinner is an agricultural chemist and has been with the bureau since 1904. He formerly was a member of the chemical staff of the Maryland Agricultural College. He has been charged with the enforcement of the beverage regulations promulgated in connection with the food and drugs act. He is a native of Maryland and was graduated from the Maryland Agricultural College and from George Washington University.

Transportation Arrangements for the British Chemists

The members of the Society of Chemical Industry of Great Britain and those of the Canadian Section who are to participate in the international session to be held on Sept. 8, in New York City, will enter the United States at Niagara Falls and on the evening of Sept. 5 will go by special train to Syracuse, where they will inspect the plant of the Solvay Process Co. The next day they are to proceed in the same cars to Albany, where connections will be made with the night boat "Berkshire," upon which accommodations for 150 have been reserved. The party will arrive at New York early the next morning, in time for the society meetings.

Members of the societies desiring to obtain accommodations on this train and on the boat, and who have not already made arrangements with their local officers, should advise Charles F. Roth, chairman of transportation for the co-ordinating committee, 52 East 41st St., New York, before Aug. 20. For members returning via the same route, a special fare upon the following certificate plan will apply.

The Trunk Line Association and the Southeastern Passenger Association have granted special rates equivalent to a fare (one way) and a half to those traveling from within their territories. Tickets can be purchased and used from Sept. 6, and the return coupon is good until midnight of Sept. 23. To obtain this reduced fare an identification certificate (which will be furnished upon application to C. L. Parsons, secretary, A.C.S., 1709 G St., N. W., Washington, D. C., or Allen Rogers, secretary, Society of Chemical Industry, Pratt Institute, Brooklyn, N. Y., respectively for these members) will be necessary and will suffice for each member, including his family.

Accommodations and arrangements for the entertainment of the visitors are in the hands of the co-ordinating committee of the American Chemical Society, with whom they are to hold the joint scientific sessions. It is expected that many of the chemists will bring their wives and daughters, and accordingly the ladies' entertainment committee, of which Mrs. L. H. Baekeland, of Yonkers, is the chairman, has an unusually complete organization and is making elaborate preparations for the entertainment of the ladies.

PROMINENT SCIENTISTS EXPECTED

At the head of the overseas delegation will be Sir William J. Pope, K.B.E., F.R.S., president of the Society of Chemical Industry, who two years ago was knighted for his valuable services in the production of mustard gas.

Among other prominent members will be Dr. Louis A. Jordan, Chevalier of the Crown of Italy, who was sent to aid the Italian Government in the making of explosives; Dr. Frederick William Atack, whose principal work has been the chemistry of dyes; Dr. Andrew McWilliams, one of the best-known steel metallurgists in Great Britain, and Dr. Andrew Smith, an explosives engineer of international reputation.

Some of the eminent Canadian chemists will be: Dr. R. F. Ruttan, past president of the Canadian Section of the society, chairman of the Advisory Council of Scientific Research and formerly vice-president of the parent society; Dr. Milton L. Hersey, one of the founders and past chairman of the Canadian Section, and Dr. C. R. Hazen, chairman of the Montreal Section.

Ceramics Work Being Expanded

Fully \$60,000 will be expended during the next twelve months at the ceramic experiment station of the U. S. Bureau of Mines at Columbus, Ohio. This sum includes with the Federal appropriations the amounts which have been contributed by industries interested in the research. In addition to the regular work of the station, the experimentation on heavy clay products and on the Georgia kaolins will be conducted at the Columbus station.

Due to the increased importance of the work at Columbus L. I. Shaw, the assistant chief chemist of the bureau, has been transferred to Columbus as chief assistant to the superintendent of the station. The vacancy in the Washington office has been filled by the designation of Dr. Andrew Stewart to act as assistant chief chemist.

Synthetic Organic Chemicals Defined

The Treasury Department has recently issued important regulations for the enforcement of the dye and chemical control section of the emergency tariff act of May 27, 1921. Among the provisions of interest to the chemical industry may be found the following:

The terms "synthetic organic chemical and synthetic organic drug," used in said section 501-a of the emergency tariff act are interpreted to apply to any substance which is known commercially as a chemical or drug and which contains carbon in chemical combination with other elements (excepting cyanides, cyanamides, carbides, carbonates and bicarbonates of metals or inorganic radicals), and which has been produced by any chemical process other than that necessary to extract, isolate or purify the substance from a natural source or to effect its separation from a more complex natural compound by hydrolysis or to form a salt.

Products obtained by fermentation, if such fermentation is carried on under controlled conditions, are considered to be synthetic organic chemicals. Distillation which simply separates a substance already formed from other substances does not make the product of such simple distillation a synthetic chemical or drug, but if the substance is subject to destructive distillation the products of such destructive distillation are considered to be synthetic organic chemicals or drugs.

In those cases where a particular substance may be either a natural or synthetic product it should be assumed that the substance is a synthetic product if it is known that the product produced is of a substantial commercial quantity. In cases of doubt the question will be referred to the department.

It is held that compounds or mixtures in part of coal-tar origin are included in the term "mixtures and compounds of such coal-tar products" as it occurs in the act, and that it was not the intent of the act to limit the term to mixtures and compounds wholly of coal-tar origin. When a product has sufficient coal-tar product mixed or combined with it to change materially its identity or character it shall be considered a "mixture or compound of such coal-tar product" within the meaning of the act.

American Peat Society to Meet in New York

The fifteenth annual convention of the American Peat Society will be held at the Hotel Commodore, in New York City, on Sept. 7, 8 and 9. Addresses will be made by well-known peat specialists of the United States and Canadian governments, by soil experts of various state experiment stations and by others interested in the engineering and bacteriologic aspects of the world's peat deposits. The program will include discussions of air-dried machine and powdered peat fuel, the cultivation of peat soils, the application of bacteriology to soil fertilization, the use of peat as a nitrogenous ingredient and conditioner of fertilizer and stock feed, the efficient handling of peat, false promotion, inefficient engineering and other subjects. An important announcement concerning the status and prospects of the industry and the society will be made by one of the officers. At the close of the meeting an opportunity will be given to visit one of the largest and most efficient peat plants in the world and to see the products being produced in commercial quantities.

French Edition of Specifications Now Available

The U. S. Department of Commerce has completed the translation and publication of the French-English edition of 61 A.S.T.M. specifications particularly applicable to export trade. These specifications form part of the Industrial Standard Series, of which the Spanish-English editions of the same specifications were the beginning. The specifications include those for rails and splice bars, structural and reinforcing steels, steel forgings and castings, steel wheels and tires, steel and iron tubes and pipe, boiler steels, wrought-iron products, pig iron, cast-iron pipe, malleable and gray-iron castings, copper wire, copper bars, spelter, bronze, cement, linseed oil and turpentine. Copies are being distributed by the Government to commercial attachés and trade commissioners, and arrangements for distribution in other channels are being considered. Copies of the specifications may be obtained by addressing the Superintendent of Documents, Washington, D. C.

New Bureau of Standards Standard Samples

A new standard sample of lead-base bearing metal No. 53 is now being issued with a provisional certificate. This sample has the approximate composition: Lead 79 per cent, tin 11 per cent and antimony 10 per cent, and contains in addition small amounts of bismuth, copper, iron and arsenic. The price of this sample is \$2 per 150 g., prepaid or parcel post c.o.d.

Renewal No. 33a of nickel steel No. 33 is also ready for distribution at the price of \$2.50 per 150 g.

Book Reviews

COPPER REFINING. By *Lawrence Addicks*. 6 x 9 in., 211 pages. New York: McGraw-Hill Book Co., Inc. Price, \$3.

If one had been asked six months ago where to find information on electrolytic refining of copper, he would have been somewhat at a loss. About the only English text on this subject, T. Ulke's "Modern Electrolytic Copper Refining," was written 20 years ago and has been out of print for some time. Texts on general metallurgy, and even treatises on the metallurgy of copper, present only the barest outline of refinery practice. For instance, Peter's "Modern Copper Smelting" contains a chapter dating from the 90's, and his later books seem to avoid the subject. Schnabel is useless. Gowland's excellent "Metallurgy of the Non-Ferrous Metals" compresses the matter into six pages.

Since Ulke's book has appeared, therefore, the only additional information available consists of articles scattered through the technical press, with perhaps the sole exception of Burns' monograph on the Great Falls Refinery.¹ Hansen, of the General Electric staff, also prepared a detailed consideration of the underlying electrochemistry (unfortunately not yet printed). Beyond this, one was forced to rely upon Greenawalt's "Hydrometallurgy of Copper," and Tobelmann's accounts of operations at Ajo.² The latter are discussing a fundamentally different problem, however; that of depositing pure copper from a sometimes impure solution, while the problem of electrolytic refining is to convert low-grade copper into one of highest purity.

It is therefore apparent that here existed a considerable gap in metallurgical literature. But to fill it was what might be called a labor of love, since it would circulate only among the more important technical libraries, and the relatively minute number of men occupied in this branch of copper production—there are only 11 refineries handling any important tonnage in the Western Hemisphere. Nevertheless the labor has been well done.

Addicks approaches the subject from an entirely different viewpoint than did Ulke. The latter neglected the chemistry and physics of the process and successfully attempted a symposium of refinery practice, showing how the various plants were laid out, and describing the minutiae of their construction. In many cases one was left wondering what reasons led to the choice of certain detail at Perth Amboy and another at Baltimore. Addicks, on the other hand, views the process from a managerial standpoint. His Chapter V on "Current Efficiency" is an instance. Current efficiency is first defined, then nine sources of loss are listed and discussed in detail. Any or all of them may be kept to a very low amount by means which are noted or are self evident to a competent designer reading the text, so that an efficiency of 99 per cent can be had if expense is no item. Good balanced operation approaches nearer 92 per cent. It is the 92 per cent which interests Addicks, and he emphasizes that a gain over this figure must not cost in other departments more than the coal it saves.

A further notable feature of the text is the pronounced stress the author places on an expense seldom mentioned, but nevertheless most important. This refers to the interest on metals tied up in the process. Such an item is of

greatest importance when figured against precious metals contained in the sludges, but an enormous mass of cheaper copper worth a far greater sum of money circulates perpetually through the plant, always in solution. Modifications to present practice are continually directed toward a reduction of this locked-up value.

A considerable portion of the text has been published serially in *CHEMICAL & METALLURGICAL ENGINEERING* during the last five years. Nevertheless, our readers will recognize the desirability of having the articles collected in a form handy for reference. The treatment of the subject is such that not only copper refinery men, but every engineer or chemist working with the electrodeposition of metal from aqueous solution, will get many valuable suggestions which he can apply directly to better his work. E. E. THUM.

Personal

W. M. BERRY of the Bureau of Standards, A. I. PHILLIPS of the American Gas Association and H. A. STRAUS, chief engineer of the Public Service Commission of Maryland, are the committee of engineers to investigate for the Maryland Public Service Commission the desirable quality of gas to be required in the city of Baltimore. Extended experiments on the efficiency of use and on other features bearing upon the general matter will be carried out in Baltimore jointly by the commission, the Baltimore Consolidated Gas & Electric Light Co. and the Bureau of Standards.

RAYMOND T. BOHN has been appointed chief chemist of the Nicetown plant of the Midvale Steel & Ordnance Co., succeeding Dr. G. L. Kelley, resigned.

S. A. COVILLE, gas engineer of the Maryland Public Service Commission, is to visit Canada and Europe investigating the influence of the standards for gas quality which have been adopted in those countries on the service to gas users. This work is in line with an extended investigation which the commission is now undertaking regarding the quality of gas to be required in Baltimore.

H. C. DICKINSON, who has been for some years chief of the automotive investigations division of the Bureau of Standards, has been granted a year's leave of absence from the bureau to become director of research of the Society of Automotive Engineers. He will, however, continue in some measure to co-operate in the Bureau of Standards' investigations by giving a small amount of his time to conference and direction of the work of this division. Work of the S.A.E. on research will not include any experimental investigations by the society itself, but will deal rather with an exchange of research information, the general study of research in progress within the industry and of interest to it, and an effort to secure proper arrangements for additional research work which is not now adequately cared for.

B. M. LARSEN has been elected a fellow in the University of Washington for electrometallurgical work in the Bureau of Mines Station at Seattle, Wash.

E. A. RICHARDSON has resigned as a member of the glass technology department, National Lamp Works of the General Electric Co., Cleveland, Ohio, to accept the position of chief chemist for the Libbey Glass Manufacturing Co., Toledo, Ohio.

WILFRED W. SCOTT has resigned as research chemist of the General Chemical Co. to accept the position of associate professor of chemistry in the Colorado School of Mines.

BRADLEY STOUGHTON, having resigned after more than eight years' service as secretary of the American Institute of Mining and Metallurgical Engineers, will resume his practice as a consulting engineer, making a specialty of financial investigations and reports to bankers, investors, directors, trustees and examining accountants on industrial plants, engineering enterprises, and iron and steel plants. His address will be, until Oct. 1, Engineering Societies' Building, 29 West 39th St., New York City.

¹*Transactions*, American Institute of Mining Engineers, 1913, vol. 46, pp. 703, 196.

²*Ibid*, 1916, vol. 55, p. 830; 1919, vol. 60, p. 22.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, Aug. 5, 1921.

Besides a slight tendency to show fractional declines, the chemical market during the past week showed signs of an early revival regardless of the mild inquiry due to the summer season. Producers of chemicals are getting business, and some of the largest interests say that the month just ended was responsible for the best volume of sales for any month of the year to date. Caustic soda has declined slightly on spot under the efforts of resellers to stimulate business. Soda ash seemed somewhat easier, but the change in spot quotations was of no importance. Producers of these two items have not announced any change in contract prices in the open market. Some of the leading caustic soda and ash plants are running as low as 15 per cent of normal, which is surely indicative that supplies are not increasing. Imported prussiate of soda experienced a period of competitive selling early in the week and business was placed at a shade under former quotations. Bichromate of soda seemed to withstand any forced selling and the market remained firm at former quotations. Bleach has attracted some interest at 2c. per lb. f.o.b. works in large drums. Foreign caustic potash has drifted slightly downward. Domestic oxalic acid is holding quite steady, with occasional slight concessions for foreign material. Sulphuric acid is moving quietly, with supplies sufficient to meet the present demand. Prices on sulphide of soda are steady enough for domestic goods, but the imported is being offered at lower prices. Camphor is moving at unchanged values. Barium chloride afloat was offered at \$47 per ton. Manufacturers of salt cake report sales as low as \$25 per ton, spot, in bulk lots. Copper sulphate has slackened somewhat since requirements for agricultural purposes have already been met.

INDUSTRIAL CONDITIONS IMPROVING

In the industrial world, all signs indicate that the period of liquidation of the raw material markets has passed. Recent changes are due mainly to conditions of supply and demand in specific lines. This is considered a normal condition. Wholesale prices of many classes of manufactures have been fully deflated. This is not true in all lines, but recent cuts in the price of steel and widespread reductions in wages indicate that adjustment in wholesale prices will not be delayed much longer. Retail prices show wide irregularities and high-cost stocks have been largely disposed of. Price stabilization is undoubtedly not far ahead. The textile industry is progressing in admirable manner. The American Woolen Co. opened its spring sales at well-maintained prices and reported a larger volume of business than last year. There has been a slight improvement noted in the steel industry. Mill operations are reported having increased 5 per cent in the Pittsburgh region. Several mills that had been closed down for some time have reopened. Freight car loadings have shown a very decided increase during the past ten days. Although there were complaints of slack business and mid-summer dullness, bank clearings held up quite well. Clearings are not far below those of last year. This is a very good indication when taking into consideration that commodity prices are very much lower than they were at this time last year. In general, the consensus is that the fall season will see a decided turn to the better in the chemical industry.

CHEMICALS

Imported caustic soda, 88-92 per cent, is quoted in most directions at 4½@4¾c. per lb. Trading has not shown much activity during the past week and in some quarters it was intimated that a firm bid at 4½c. would be accepted on a round lot. The latter figure is equivalent to the pre-war price on this material. Yellow prussiate of potash was offered

at lower figures by dealers and reports were current that small-lot sales have gone through on the basis of 2½c. per lb. The general range is from 2½@2¾c. per lb., depending upon the seller. The red variety is quiet, with sellers at 28@30c. per lb. Spot bichromate of soda is obtainable at 8c. per lb. and some sales have been recorded on this basis. Odd lots might be purchased at 7¾c. per lb. on a firm bid, but dealers were not inclined to name this price in the open market. Offerings were not heavy, but appeared to be sufficient to meet the current extent of the consuming demand. Prices on spot caustic soda have drifted to a lower level on resale stock. Prominent dealers quoted the market for standard brands at \$3.65@3.70 per 100 lb., but in some directions it was stated that \$3.60 could be done ex-dock New York. The general demand has not shown much activity during the past week and while it is not believed that resale supplies are heavy, there is a keener state of competition among the holders. Contract prices remain unchanged at 3¼c. per lb., basis 60 per cent, f.o.b. works.

Scattered trading in nitrite of soda was reported at 7c. per lb., with sellers generally quoting 7@7¼c. in the open market. Rumors were current that round lots might be purchased at slight concessions, but buyers are showing very little interest beyond the limit of actual requirements. Imported prussiate of soda showed somewhat of a decline during the beginning of the week, but strengthened considerably at the close. Sales have been reported at 11¼@12c. per lb., with most sellers asking the outside figure. Foreign shipments are offered on the basis of 1½c. per lb. c.i.f. New York. Imported sulphide of soda is being offered by dealers at 4½c. per lb. for the fused and 5½c. for the broken. Odd lots of the latter material could probably be purchased at 5@5½c. on a firm offer. Resale lots of light soda ash in single bags were a shade easier on spot, with sellers quoting \$1.90 per 100 lb., although 2c. per lb. was the prevailing asking price in most directions. Foreign shipments were offered at 1½c. per lb. c.i.f. and in one quarter 1¼c. was named for prompt shipment from England.

Leading factors in cobalt oxide report sales at \$2.35@2.45 per lb., depending on the quantity. Prevailing quotations are the lowest named so far this year. Dealers of cream of tartar quote 28½c. per lb. and might do a little better on a firm offer. Producers continue to ask 33c. per lb., but are not getting much business at this price. Odd lots of oxalic acid of foreign and domestic manufacture are quoted by second hands at 17@17½c. per lb. Some producers are accepting business at the outside figure at the works. The extreme range of prices is from 17@19c. per lb., depending entirely upon the quantity, brand and seller. Buyers of tin oxide are showing a little more interest at the late reduction named by producers. Small-lot sales were reported at 38c. per lb.

COAL-TAR PRODUCTS

The coal-tar products market during the past week presented an appearance of calmness on the surface, but the undertone was diversified, making the situation somewhat difficult to analyze. In some quarters business is fairly active. Some products seem to be in demand, and where the condition holds true, brisk selling is taking place. Other products are dull and cannot be moved even at price concessions. Inquiries, in general, are more numerous, with the foreign element showing greater interest. Small-lot orders still form the bulk of sales, but discriminating consumers are showing an inclination to buy ahead when they are convinced that the product is selling at the rock-bottom figure. The low-priced resale material is being cleaned out of the market, but on some products manufacturers are feeling the competition quite keenly. The full importance of the action of the House on the dyestuff measure is now being realized both by manufacturers and consumers, with the result that the mental attitude of the trade is most unsettled. The majority of makers feel that full protection will be accorded them, but some consumers are reserving purchases until legislative action of a more definite nature is taken.

Sales of fair-sized lots of aniline oil were made at 18c. per lb. Smaller quantities are moving at higher prices. In some quarters 24c. per lb. is asked, but little buying is

being done at this level. The resale market seems well supplied, and with the present weak condition, a slight reduction is very probable. Producers of *benzene* are firm at 27@33c. per gal. for prime goods and 25@30c. for the 90 per cent. The present demand is exceeding the supply. Many coke ovens are still shut down with a consequent curtailment of supplies. Sales of fair-sized lots of *beta naphthol* were made at 34c. per lb. Odd lots of resale goods can be picked up as low as 32½c., but usually this material has been found to be old goods of inferior quality. The price range on *phenol* is varied at 9½@14c. per lb., depending upon seller, with resale lots at the lower level. Official Government resellers are quoting 12c. per lb. The demand is light and competition rather keen. Stocks of *dimethylaniline* are not as large as formerly, and offerings were heard at the close of the week at 42c. per lb., with many disposed to ask up to 44@45c. Producers of *diphenylamine* ask up to 67c. per lb. Some odd lots were known to have sold down to 55c. per lb. Resellers are stronger in their views and it is doubtful if the 60@61c. price could easily be done. Supplies of *eresylic acid* are plentiful, but the demand showed a spurt, with some contract business placed. Consumers have shown more inclination to buy ahead. The 97-99 per cent is quoted at 68@75c. per gal.

WAXES

Dullness continues to feature the market in *beeswax*. Prices, however, remain unchanged and nominal at former levels. Pure refined white wax is quoted at 40@45c. per lb. African crude ranges from 14@16c. per lb. South American brands are quoted on a basis of 21@25c. per lb. With trading practically at a standstill, the market on *carnauba wax* presents a weak tone and prices are purely nominal. No. 1 is available at 40@42c. per lb. and the No. 2 at 38@40c. No. 2 North Country was nominal at 25c. per lb. No. 3 North Country closed at 13½c. per lb. Firmer cables on *Japan wax* were received from the Orient, which resulted in the withdrawal of some offerings from the market. Spot stocks, however, were quotably unchanged at 16½@17c. per lb. The demand was of a hand-to-mouth character. Weakness in *paraffine wax* was the ruling feature of the market. Trading continues limited to small lots and quotations are unsteady. While scale wax was quoted at 2c. per lb., carlots, f.a.s. N. Y., it was stated that this price could be shaded on a firm bid for a round lot. Match wax closed unchanged at 3¼c. per lb. The other grades of wax were also wholly nominal.

VEGETABLE OILS

While crushers of *castor oil* maintained prices on the basis of 9½c. per lb. for the No. 3 quality in barrels, outside lots were available at concessions. The recent advance in castor seed, however, has brought about a firmer undertone. There were offerings of *chinawood oil* for August arrival at New York at 11¼c. per lb., in barrels, with the market barely steady as a result of the prevailing quiet conditions. In some directions it was intimated that 11c. might be done for August oil. Spot material remained scarce and quotations of 13@14c. per lb. were merely nominal. August-September shipments from the Orient closed at 10@10¼c. c.i.f. New York, barrels included. No important transactions in the market were reported for *coconut oil*. Prices named showed little change. Manila operators ask on a basis of 7¼c. per lb., loose, August-September shipment, c.i.f. Pacific Coast, while 7½c. was asked c.i.f. N. Y. arrivals. Offerings of *crude corn oil* in the Middle West were scanty and prices were more or less nominal around 7@7¼c. per lb., sellers' tanks, f.o.b. Chicago, September delivery. Edible *olive oil* on spot was unsettled at \$1.90@\$2.25 per gal., with offerings in some directions rather liberal. Denatured on spot closed at \$1.25 per gal. *Lagos palm oil* was advanced to 6¾c. per lb. c.i.f. N. Y., the rise being in sympathy with higher prices in Liverpool. *Niger oil* was marked up to 5¾c. per lb. c.i.f. N. Y., prompt shipment from abroad. Domestic crude *peanut oil* closed at 7½@7¾c. per lb., prime basis, tank cars, f.o.b. mills, although recent business was placed at 7¼c. Oriental oil for prompt shipment from the Coast was scarce and closing prices were advanced to 7¼@7½c. per lb., sellers' tanks.

The St. Louis Market

ST. LOUIS, Mo., Aug. 5, 1921.

There has been a very pronounced improvement in the activity of the drug and fine chemical market and buying has measurably increased, indicating that the summer lull has been passed and that consumers' stocks are very low, and furthermore that the resale lots are diminishing. The market on heavy chemicals was quite active the past two weeks and with inquiries coming from many of the larger consumers for the first time in many months, the future on heavy chemicals is decidedly optimistic. An appreciable amount of business is originating from the dye and textile manufacturers, and as a whole the present condition gives a very promising appearance for the future.

Caustic soda demand has been very good. Several of the large contract buyers are beginning to take out their allotments. Carload prices range from \$3.75@\$4.50 per 100 lb., basis 73-75 per cent solid, f.o.b. point of production. *Soda ash* continues at the manufacturers' prevailing schedule. *Bicarbonate of soda* demand has been very dull with prices holding at \$2.75 per 100 lb.

The activity in *carbon bisulphide* still prevails and a very nice business is being transacted. *Hpyo* continues in a routine way. *Sulphur* continues to hold firm at \$2 per 100 lb. for the commercial in bags, with routine demand.

DRUGS AND PHARMACEUTICALS

The demand for *bismuth salts* has tremendously increased and manufacturers are in good position to fill orders promptly. Some certain *citrate salts* continue to move freely. Producers have reduced their price on *cream of tartar*, in spite of which the demand has been very good. A very good demand for *ether* from the hospital trade is being enjoyed. *Glycerine* has again declined and now holds at 14c. per lb. for both spot and contract with a fair demand. *Hydrogen peroxide* continues to move steadily through routine channels. *Iodides* have shown a fair increase. *Salicylates* are holding their own. *Sodium benzoate* is not moving as manufacturers expected. However, there has been a slight improvement. Factors have reduced their price on *strychnine*, but little is expected to result from this reduction, for the use of this commodity is limited and buyers will take on supplies only in about the same volume. *Zinc oxide* prices have not changed since June 27, although the demand during July for both leaded and lead-free fell off considerably. The manufacturers predict a picking up in the lead-free in the next two weeks and base these predictions on the increased demand since Aug. 1. *Zinc stearate* demand continues to increase.

ACIDS

Producers of heavy acids report a decided increase and are very optimistic regarding the future. *Sulphuric acid* is moving in a large volume to the oil-refining trade. Apparently consumers of heavy acids are again in operation and their stocks on hand are exhausted. Many inquiries for *benzoic acid* are being received and in many instances resulting in business. The market for *carbolic acid* retains the same steady tone that has been noted for some time past, with a fair inquiry and demand. The extreme hot weather which has recently prevailed has caused some increase in the demand for small quantities of *citric acid*. However, the situation still lacks any appreciable change. The demand for *phosphoric acid* has improved. Apparently the soft-drink manufacturers are substituting *tartaric acid* for *citric acid* and lately the consumption has been heavy.

VEGETABLE OILS AND PAINT MATERIALS

Linseed oil, after a temporary rise to 81c., has settled to 78c., basis raw. The demand for spot oil is fair, with no contracting being done. *Castor oil* enjoys a routine demand, with an advance of price to 11¼c., in returnable drums for No. 1 U.S.P. *Turpentine* demand continues very fair considering the dull period the paint trade is now experiencing. The price has stiffened continuously the past week and today is quoted at 61½c. per gal.

Lithopone continues in fair demand with price the same. *Red oxides* have been in fair movement the past two weeks for the first time this year.

The Iron and Steel Market

PITTSBURGH, Aug. 5, 1921.

Gradual improvement in the demand upon the steel mills can be seen, but the improvement is very slow, particularly in tonnage. It is in the lighter lines that the improvement is more noticeable, particularly in sheets and tubular goods. Wire products recently showed a decided gain in demand, but the demand has decreased somewhat in the past few days. In the heaviest lines, rails and shapes, there is practically no change, and thus tonnage does not show much gain. The best guess is that the production of steel ingots in July was just under 20 per cent of capacity, taking the month as a whole, but production at the middle of the month was somewhat under the average. The first half of August will probably show a rate measurably above 20 per cent.

The character of the demand upon the steel mills is still plainly marked as being for common everyday consumption, the increase in demand during the past three weeks being due to further depletion of stocks of steel in buyers' hands as well as distribution of stocks of various wares made of steel.

COMPETITION AND PRICES

There is not merely an "open market" in steel products, with each seller naming a particular price against each inquiry, but there is strenuous competition. The competition does not take the form of price slashing, the policy being rather reserved in that respect, and steel prices are now sagging rather than definitely declining. On the whole the steel market has really gone off rather gently. While there has been declines in some products that appeared rather spectacular, the fact in most cases was that what appeared like a straight reduction was really the open recognition of price-cutting that had been growing gradually. The general pace of decline is certainly much less rapid now and it is quite unlikely there will be any clear-cut breaks in future. The price on a 500-ton lot today may become the price on a 100-ton lot a fortnight hence and in a week or two the price on a single carload. Carload prices now may be quoted at 1.75c. for bars, 1.85c. for shapes and plates and 2.40c. for hoops or hot-rolled strips. In sheets the highest prices seriously asked are 2.40c. on blue annealed, 3.25c. on black and 4.25c. on galvanized. On some orders not particularly large as low as 3c. has been done on black and 4c. on galvanized, while it is rumored that in one or two special cases 3.75c. has been done on galvanized. An order of equal size in black would hardly bring out a price of 2.75c., the trend in close competition being to narrow the spread between black and galvanized to less than \$1 per 100 lb. The open quotation on plain wire is 2.50c., with \$2.75 regarded as the open market on rails.

Setting together the two facts that mills are rather reserved in cutting prices and altogether avoid any slashing, while it is generally claimed that to the average or typical mill present prices represent a loss, it may be surmised that mills are making quotations on a theoretical or prospective cost, based on what they expect to be able to do when they secure a fair rate of operation. With a mill operating at 15 or 20 or 30 per cent the actual computation of cost is not indicative of what could be done under reasonable conditions. The mills are in a condition never before experienced, for before the war it was a dictum that it was not feasible to operate a mill at less than about 50 per cent of capacity.

PIG IRON

A sale of 2,000 tons of basic iron made by a valley producer at \$18 furnace took \$1 off the quotable market. Bessemer is offered at \$20 valley, against \$20.50 a week ago. Foundry remains nominally quotable at \$19.50, though a firm offer for a round tonnage at a considerably lower price would probably bring results. The \$18 basic price is a phenomenon, since the transportation cost of assembling the coke, ore and limestone at a valley furnace is more than \$10. Sales at so much under present cost represent a desire to liquidate and an expectation that costs will be lower when it becomes necessary to make more iron. All the merchant furnaces in the valleys are idle.

General Chemicals

Sodium bisulphite powdered, U.S.P..... lb.	.05 - .05½	.05½ - .06
Sodium borate (borax)..... lb.	.05½ - .06	.06½ - .06½
Sodium carbonate (sal soda)..... 100 lb.	1.90 - 2 00	2 10 - 2 40
Sodium chl rate..... lb.	.07½ - .07½	.08 - .08½
Sodium cyanide..... lb.	.19½ - .21	.22 - 30
Sodium fluoride..... lb.	.11½ - .12	.12 - .13½
Sodium hydroxide (caustic soda)..... 100 lb.	3.60 - 3 70	3 80 - 4 40
Sodium hypsulphite..... lb.		.03½ - .03½
Sodium nitrite..... 100 lb.	2.10 -	2 30 -
Sodium nitrate..... lb.	.07 - .07½	.07½ - .08
Sodium peroxide, powdered..... lb.	.25 - .26	.27 - 30
Sodium phosphate, dibasic..... lb.	.04½ - .04½	.05 - .05½
Sodium potassium tartrate (Rochelle salts)..... lb.		.26 - .27
Sodium prussiate, yellow..... lb.	.11½ - .12	.12½ - .13
Sodium silicate, solution (40 deg.)..... 100 lb.	1.00 - 1 15	1 25 - 1 40
Sodium silicate, solution (60 deg.)..... lb.	.02½ - .03	.03½ - .03½
Sodium sulphate, crystals (Glauber's salt) 100 lbs.	1 50 - 1 75	2 00 - 2 25
Sodium sulphide, fused, 60-62 per cent (conc.) lb.	.04½ - .04½	.05 - .05½
Sodium sulphite, crystals..... lb.	.03½ - .04	.04½ - .04½
Strontium nitrate, powdered..... lb.	.15 - .15½	.16 - .17
Sulphur chl ride, red..... lb.	.07 - .07½	.07½ - .08
Sulphur, crude..... ton	20 00 - 22 00	
Sulphur dioxide, liquid, cylinders extra..... lb.	.08 - .08½	.09 - .10
Sulphur (sublimed), flour..... 100 lb.		2 25 - 3 10
Sulphur, roll (brimstone)..... 100 lb.		2 00 - 2 75
Tin bichloride, 50 per cent..... lb.	.18 - .19	
Tin oxide..... lb.		.38 - .40
Zinc carbonate, precipitate..... lb.	.15½ - .16	.16½ - .17
Zinc chloride, gran..... lb.	.11 - .11½	.11½ - .12
Zinc cyanide..... lb.	.45 - .49	.50 - .60
Zinc dust..... lb.	.11½ - .11½	.11½ - .12½
Zinc oxide, XX..... lb.	.07½ - .07½	.08 - .09
Zinc sulphate..... 100 lb.	3.00 - 3 25	3 30 - 3 50

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude..... lb.	\$1 10 - \$1 15
Alpha-naphthol, refined..... lb.	1 25 - 1 30
Alpha-naphthylamine..... lb.	.35 - .40
Aniline oil, drums extra..... lb.	.18 - .21
Aniline salts..... lb.	.25 - .28
Anthracene, 80% in drums (100 lb.)..... lb.	.75 - 1 00
Benzaldehyde U.S.P..... lb.	1 00 - 1 25
Benzidine, base..... lb.	.85 - 1 00
Benzidine sulphate..... lb.	.75 - .85
Benzoic acid, U.S.P..... lb.	.60 - .65
Benzoate of soda, U.S.P..... lb.	.55 - .60
Benzene, pure, water-white, in drums (100 gal.)..... gal.	.27 - .32
Benzene, 90%, in drums (100 gal.)..... gal.	.25 - .28
Benzyl chloride, 95-97%, refined..... lb.	.25 - .27
Benzyl chloride, tech..... lb.	.20 - .23
Beta-naphthol benzoate..... lb.	3 50 - 4 00
Beta-naphthol, sublimed..... lb.	.70 - .75
Beta-naphthol, tech..... lb.	.32½ - .37
Beta-naphthylamine, sublimed..... lb.	1 75 - 1 80
Cresol, U. S. P., in drums (100 lb.)..... lb.	.16 - .18
Ortho-cresol, in drums (100 lb.)..... lb.	.25 - .27
Cresylic acid, 97-99%, straw color, in drums..... gal.	.68 - .75
Cresylic acid, 95-97%, dark, in drums..... gal.	.65 - .70
Cresylic acid, 50%, first quality, drums..... gal.	.45 - .50
Dichlorobenzene..... lb.	.06 - .09
Diethylaniline..... lb.	1 20 - 1 25
Dimethylaniline..... lb.	.42 - .50
Dinitrobenzene..... lb.	.26 - .28
Dinitrochlorobenzene..... lb.	.20 - .30
Dinitronaphthalene..... lb.	.30 - .40
Dinitrophenol..... lb.	.35 - .40
Dinitrotoluene..... lb.	.27 - .30
Dip oil, 25%, ear lots, in drums..... gal.	.40 - .45
Diphenylamine..... lb.	.60 - .65
H-acid..... lb.	1 15 - 1 25
Meta-phenylenediamine..... lb.	1 15 - 1 20
Monochlorobenzene..... lb.	.12 - .14
Monoethylaniline..... lb.	1 75 - 1 85
Naphthalene crushed, in bbls..... lb.	.06½ - .08
Naphthalene, flake..... lb.	.06½ - .08
Naphthalene, balls..... lb.	.08 - .09
Naphthionic acid, crude..... lb.	.70 - .75
Nitrobenzene..... lb.	.12 - .15
Nitro-naphthalene..... lb.	.30 - .35
Nitro-toluene..... lb.	.16 - .18
Ortho-amidophenol..... lb.	3 10 - 3 20
Ortho-dichlor-benzene..... lb.	.15 - .20
Ortho-nitro-phenol..... lb.	.80 - .85
Ortho-nitro-toluene..... lb.	.15 - .20
Ortho-toluidine..... lb.	.20 - .25
Para-amidophenol, base..... lb.	1 40 - 1 45
Para-amidophenol, HCl..... lb.	1 60 - 1 75

Para-dichlorobenzene..... lb.	.15 - .20
Paranitroaniline..... lb.	.75 - .80
Para-nitrotoluene..... lb.	.85 - .95
Para-phenylenediamine..... lb.	1 70 - 1 95
Para-toluidine..... lb.	1 25 - 1 40
Phthalic anhydride..... lb.	.50 - .60
Phenol, U. S. P., drums..... lb.	.09½ - .11
Pyridine..... gal.	2 00 - 3 50
Resorcinol, technical..... lb.	1 60 - 1 65
Resorcinol, pure..... lb.	2 25 - 2 30
Salicylic acid, tech., in bbls..... lb.	.19 - .22
Salicylic acid, U. S. P..... lb.	.20 - .25
Salol..... lb.	.75 - .80
Solvent naphtha, water-white, in drums, 100 gal..... gal.	.25 - .28
Solvent naphtha, rude, heavy, in drums, 100 gal..... gal.	.14 - .16
Sulphanilic acid, crude..... lb.	.30 - .35
Tolidine..... lb.	1 25 - 1 35
Toluidine, mixed..... lb.	.40 - .45
Toluene, in tank cars..... gal.	.25 - .28
Toluene, in drums..... gal.	.28 - .31
Xylidines, drums, 100 gal..... lb.	.40 - .45
Xylene, pure, in drums..... gal.	.40 - .45
Xylene, pure, in tank cars..... gal.	.45 -
Xylene, commercial, in drums, 100 gal..... gal.	.33 - .35
Xylene, commercial, in tank cars..... gal.	.30 -

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark..... lb.	\$0 24 - \$0 25
Beeswax, refined, light..... lb.	.27 - .28
Beeswax, white pure..... lb.	.40 - .45
Carnauba, Florida..... lb.	.58 - .60
Carnauba, No. 2, North Country..... lb.	.25 - .26
Carnauba, No. 3, North Country..... lb.	.13½ - .14
Japan..... lb.	.16 - .16½
Montan, crude..... lb.	.06½ - .06½
Paraffine waxes, crude match wax (white) 105-110 m.p..... lb.	.03½ - .03½
Paraffine waxes, crude, scale 124-126 m.p..... lb.	.02 -
Paraffine waxes, refined, 118-120 m.p..... lb.	.03 - .03½
Paraffine waxes, refined, 125 m.p..... lb.	.03½ - .03½
Paraffine waxes, refined, 128-130 m.p..... lb.	.04 - .04½
Paraffine waxes, refined, 133-135 m.p..... lb.	.04½ - .05
Paraffine waxes, refined, 135-137 m.p..... lb.	.05½ - .06
Stearic acid, single pressed..... lb.	.09 -
Stearic acid, double pressed..... lb.	.09½ -
Stearic acid, triple pressed..... lb.	.10 - .10½

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl..... 280 lb.	\$4 85 -
Rosin E-I..... 280 lb.	4 90 - 5 20
Rosin K-N..... 280 lb.	5 30 - 5 75
Rosin W, G-W, W..... 280 lb.	6 50 - 7 25
Wood rosin, bbl..... 280 lb.	6 25 -
Spirits of turpentine..... gal.	.63 -
Wood turpentine steam dist..... gal.	.61 -
Wood turpentine, dest. dist..... gal.	.59 -
Pine tar pitch, bbl..... 200 lb.	- 7 00
Tar, kiln burned, bbl. (500 lb.)..... bbl.	- 11 50
Retort tar, bbl..... 500 lb.	- 11 50
Rosin oil, first run..... gal.	.35 -
Rosin oil, second run..... gal.	.37 -
Rosin oil, third run..... gal.	.41 -
Pine oil, steam dist., sp.gr. 0.930-0.940..... gal.	\$1 80
Pine oil, pure, dest. dist..... gal.	1 50
Pine tar oil, ref., sp.gr. 1.025-1.035..... gal.	.46
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla..... gal.	.35
Pine tar oil, double ref., sp.gr. 0.965-0.990..... gal.	.75
Pine tar, ref., thin, sp.gr. 1.080-1.960..... gal.	.35
Turpentine, crude, sp. gr., 0.900-0.970..... gal.	1 20
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990..... gal.	.35
Pinewood creosote, ref..... gal.	.52

Solvents

73-76 deg., steel bbls. (85 lb.)..... gal.	\$0 41
70-72 deg., steel bbls. (85 lb.)..... gal.	.39
68-70 deg., steel bbls. (85 lb.)..... gal.	.38
V. M. and P. naphtha, steel bbls. (85 lb.)..... gal.	.30

Crude Rubber

Para-Upriver fine..... lb.	\$0 16 - .17
Upriver coarse..... lb.	.09 - .09½
Upriver caucho ball..... lb.	.11½ - .12
Plantation—First latex crepe..... lb.	.14 -
Ribbed smoked sheets..... lb.	.12 - .12½
Brown crepe, thin, clean..... lb.	.15 -
Amber crepe No. 1..... lb.	.17 -

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls..... lb.	\$0 09½ - \$0 09½
Castor oil, AA, in bbls..... lb.	.10 - .10½
China wood oil, in bbls. (f.o.b. Pac. coast)..... lb.	.12 - .12½
Cocoonut oil, Ceylon grade, in bbls..... lb.	.09½ - .10
Cocoonut oil, Cochon grade, in bbls..... lb.	.10½ - .10½
Corn oil, crude, in bbls..... lb.	.08½ - .08½
Cottonseed oil, crude (f. o. b. mill)..... lb.	.07½ - .08
Cottonseed oil, summer yellow..... lb.	.09 - .09½
Cottonseed oil, winter yellow..... lb.	.09½ -
Linseed oil, raw, ear lots (domestic)..... gal.	.75 - .76
Linseed oil, raw, tank cars (domestic)..... gal.	.69 - .70
Linseed oil, in 5-bbl lots (domestic)..... gal.	.77 - .78

Olive oil, Denatured.....	gal.	\$1.25	—	\$1.30
Palm, Lagos.....	lb.	.06	—	.07
Palm, Niger.....	lb.	.05	—	.05
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.07	—	.07
Peanut oil, refined, in bbls.....	lb.	.10	—	.10
Rapeseed oil, refined in bbls.....	gal.	.90	—	.92
Rapeseed oil, blown, in bbls.....	gal.	.94	—	.95
Soya bean oil (Manchurian), in bbls. N. Y.....	lb.	.08	—	
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.06	—	

FISH

Light pressed menhaden.....	gal.	\$0.42	—	
Yellow bleached menhaden.....	gal.	.44	—	
White bleached menhaden.....	gal.	.46	—	
Blown menhaden.....	gal.	.50	—	

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.....	net ton	\$24.00	—	30.00
Barytes, ground, off color, f.o.b. Kings Creek.....	net ton	22.00	—	26.00
Barytes, crude, 88% @ 94% ba., Kings Creek.....	net ton	10.00	—	12.00
Barytes, floated, f.o.b. St. Louis.....	net ton	26.50	—	28.00
Barytes, crude, first grade, Missouri.....	net ton	7.00	—	
Blanc fixe, dry.....	lb.	.04	—	.04
Blanc fixe, pulp.....	net ton	45.00	—	55.00
Casein.....	lb.	.0	—	.07
Chalk, domestic, extra light.....	lb.	.04	—	.05
Chalk, domestic, light.....	lb.	.04	—	.04
Chalk, domestic, heavy.....	lb.	.03	—	.04
Chalk, English, extra light.....	lb.	.04	—	.05
Chalk, English, light.....	lb.	.04	—	.05
Chalk, English, dense.....	lb.	.04	—	.04
China clay (kaolin) crude, f.o.b. mines, Georgia.....	net ton	8.00	—	10.00
China clay (kaolin) washed, f.o.b. Georgia.....	net ton	12.00	—	15.00
China clay (kaolin) powdered, f.o.b. Georgia.....	net ton	18.00	—	22.00
China clay (kaolin) crude f.o.b. Virginia points.....	net ton	8.00	—	12.00
China clay (kaolin) ground, f.o.b. Virginia points.....	net ton	15.00	—	25.00
China clay (kaolin), imported, lump.....	net ton	12.00	—	20.00
China clay (kaolin), imported, powdered.....	net ton	20.00	—	25.00
Feldspar, crude, f.o.b. Maryland and North Carolina points.....	net ton	5.00	—	7.50
Feldspar, crude, f.o.b. Maine.....	net ton	7.50	—	10.00
Feldspar, ground, f.o.b. Maine.....	net ton	21.00	—	23.00
Feldspar, ground, f.o.b. North Carolina.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. N. Y. State.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. Baltimore.....	net ton	27.00	—	30.00
Fullers earth, f.o.b. Mies.....	net ton	16.00	—	17.00
Fullers earth, granular, f.o.b. Ia.....	net ton	15.00	—	18.00
Fullers earth, powdered, f.o.b. Fla.....	net ton	18.00	—	
Fullers earth, imported, powdered.....	net ton	24.00	—	27.00
Graphite, Ceylon lump, first quality.....	lb.	.07	—	.07
Graphite, Ceylon chip.....	lb.	.05	—	.05
Graphite, high grade amorphous crude.....	lb.	.02	—	.03
Magnesite, calcined.....	per ton	66.00	—	70.00
Pumice stone, imported, lump.....	lb.	.04	—	.50
Pumice stone, domestic lump.....	lb.	.05	—	.05
Pumice stone, ground.....	lb.	.06	—	.07
Quartz (acid tower) first to head, f.o.b. Baltimore.....	net ton		—	10.00
Quartz (acid tower) 1 1/2 @ 2 in., f.o.b. Baltimore.....	net ton		—	14.00
Quartz (acid tower) rice, f.o.b. Baltimore.....	net ton		—	17.00
Quartz, lump, f.o.b. North Carolina.....	net ton	5.00	—	7.50
Shellac, orange fine.....	lb.	.52	—	.53
Shellac, orange superfine.....	lb.	.55	—	.56
Shellac, A. C. garnet.....	lb.	.44	—	.45
Shellac, T. N.....	lb.	.45	—	.45
Soapstone.....	ton	12.00	—	15.00
Sodium chloride.....	long ton	12.50	—	13.00
Talc, paper-making grades, f.o.b. Vermont.....	ton	11.00	—	20.00
Talc, roofing grades, f.o.b. Vermont.....	ton	8.50	—	13.00
Talc, rubber grades, f.o.b. Vermont.....	ton	11.00	—	18.00
Talc, powdered, Southern, f.o.b. cars.....	ton	10.00	—	14.00
Talc, imported.....	ton	30.00	—	40.00
Talc, California talcum powder grade.....	ton	18.00	—	40.00

Refractories

Bauxite brick, 56% Al, f.o.b. Pittsburgh.....	per ton	\$37.50—40.00
Carborundum refractory brick, 9-in.	1,000	1250.00
Chrome brick, f.o.b. Eastern shipping points.....	net ton	60
Chrome cement, 40-45% Cr ₂ O ₃	net ton	30-32
Chrome cement, 40-45% Cr ₂ O ₃ , sacks, in ear lots, f.o.b. Eastern shipping points.....	net ton	33-35
Fireclay brick, 1st quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	36-40
Fireclay brick, 2nd quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	30-35
Magnesite brick, 9-in. straight.....	net ton	70
Magnesite brick, 9-in. arches, wedges and keys.....	net ton	77
Magnesite brick, soaps and splits.....	net ton	98
Silica brick, 9-in. sizes, f.o.b. Chicago district.....	1,000	42-45
Silica brick, 9-in. sizes, f.o.b. Birmingham district.....	1,000	45-50
Silica brick, 9-in. sizes, f.o.b. Mt. Union, Pa.....	1,000	35-38

Ferro-Alloys

All f.o.b. Works

Ferro-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.....	net ton	\$200.00 — \$225.00
Ferrochrome per lb. of Cr. contained, 6-8% carbon, earlots.....	lb.	14 —
Ferrochrome, per lb. of Cr. contained, 4-6% carbon, earlots.....	lb.	15 —
Ferromanganese, 70-80% Mn, domestic.....	net ton	65.00 — 70.00
Ferromanganese, 70-80% Mn, English.....	net ton	65.00 — 70.00
Spiegeleisen, 18-22% Mn.....	net ton	26.00 — 27.00
Ferromolybdenum, 50-60% Mo, per lb. of Mo.....	lb.	2.50 —
Ferrosilicon, 10-15%.....	net ton	40.00 — 42.00
Ferrosilicon, 50%.....	net ton	65.00 — 68.00
Ferrosilicon, 75%.....	net ton	135.00 — 138.00
Ferrotungsten, 70-80%, per lb. of contained W.....	lb.	.45 — .50
Ferroumium, 35-50% of U, per lb. of U content.....	lb.	6.00 —
Ferrovandium, 30-40% of V, per lb. of contained V.....	lb.	4.25 — 4.50

Ores and Semi-finished Products

All f.o.b. New York, Unless Otherwise Stated

Bauxite, 52% Al content.....	net ton	\$8.00 — \$10.00
Chrome ore, Calif. concentrates, 50% min. Cr ₂ O ₃	unit	.30 — .33
Chrome ore, 50% Cr ₂ O ₃ , f.o.b. Atlantic seaboard.....	unit	30 — .33
Coke, foundry, f.o.b. ovens.....	net ton	4.00 — 4.50
Coke, furnace, f.o.b. ovens.....	net ton	2.75 — 3.00
Coke, petroleum, refinery, Atlantic seaboard.....	net ton	14.00 — 15.00
Fluorspar, lump, f.o.b. mines, New Mexico.....	net ton	12.50 —
Fluorspar, standard, domestic washed gravel Kentucky and Illinois mines.....	net ton	20.00 —
Ilmenite, 52% TiO ₂ , per lb. ore.....	lb.	.01 — .01
Manganese ore, 50% Mn, c.i.f. Atlantic seaport.....	unit	.22 —
Manganese ore, chemical (MnO ₂).....	net ton	50.00 — 55.00
Molybdenite, 85% MoS ₂ , per lb. of MoS ₂ , N. Y.....	lb.	.55 — .60
Monazite, per unit of ThO ₂ , c.i.f., Atlantic seaport.....	unit	30.00 —
Pyrites, Spanish, fines, c.i.f., Atlantic seaport.....	unit	.12 — .12
Pyrites, Spanish, furnace size, c.i.f. Atlantic seaport.....	unit	.12 — .12
Pyrites, domestic, fines, f.o.b. mines, Ga.....	unit	.11 — .12
Rutile, 95% TiO ₂ per lb. ore.....	lb.	.15 —
Tungsten, scheelite, 60% WO ₃ and over, per unit of WO ₃ (nominal).....	unit	2.75 — 3.00
Tungsten, Wolframite, 60% WO ₃ and over, per unit of WO ₃ , N. Y. C.....	unit	3.00 — 3.25
Uranium ore (carnotite) per lb. of U ₃ O ₈	lb.	1.50 — 2.50
Uranium oxide, 96% per lb. contained U ₃ O ₈	lb.	2.25 — 2.50
Vanadium pentoxide, 99%.....	lb.	12.00 — 14.00
Vanadium ore, per lb. of V ₂ O ₅ contained.....	lb.	1.00 —
Zircon, washed, iron free.....	lb.	.03 —

Non-Ferrous Metals

New York Markets

	Cents per Lb.
Copper, electrolytic.....	12.00
Aluminum, 98 to 99 per cent.....	24.50@25
Antimony, wholesale lots, Chinese and Japanese.....	4
Nickel, ordinary (ingot).....	41.00
Nickel, electrolytic.....	44.00
Monel metal, spot and blocks.....	35.00

Financial, Construction and Manufacturers' News

Construction and Operation

California

BURBANK—The Western Glass Products Co., Hibernian Bldg., has awarded a contract to the Frank Meline Co., 6777 Hollywood Blvd., for the erection of a new 1- and 2-story, brick and steel plant, 100 x 500 ft., at Burbank, comprising an initial plant unit of a proposed large group of buildings.

BURBANK—The American Aluminum Metal Products Co., Los Angeles, is having plans prepared by Richard D. King, 519 Van Nuys Bldg., Los Angeles, for the erection of its proposed new plant at Burbank, the initial work to consist of a series of 7 buildings. The company has a 5-acre tract, and additional structures will be erected at a later date.

Delaware

WILMINGTON—The Atlas Powder Co., du Pont Bldg., has acquired a substantial interest in the United States Flashless Powder Co., with plant at Carreroft, near Wilmington, and in the future the companies will work in close co-operation. Operations at the plant will be continued as heretofore.

Florida

TAMPA—The Southern Bottle Mfg. Co., recently organized with a capital of \$150,000, has awarded a contract to Oatley & Jones, Tampa, for the erection of its proposed new plant at Gary, near Tampa, 1-story, 60x150 ft., with wing extension, 36x52 ft. I. F. Jones is president.

TAMPA—The Grass Fiber Pulp Co. is perfecting plans for the erection of a new plant at Leesburg, Fla., for the manufacture of paper pulp from saw grass. W. F. Stovall is president.

TAMPA—The Nu-Tex Brick Co. has commenced the construction of a local plant to be equipped for an initial daily capacity of about 30,000 bricks per day. It is proposed to place the plant in service at the earliest possible date.

CHIPLEY—The Chipley Leather Mfg. Co., recently incorporated, has awarded a contract for the erection of its proposed new local plant on property lately acquired, with initial structure to be 75x125 ft. The factory will be equipped as a tannery and leather finishing plant for the production of leather specialties from fish skins. C. B. Dunn is president, and Frank Tuttle, general manager.

Illinois

CHICAGO—The American Tar Products Co., 208 South La Salle St., is completing plans for the erection of a new 1- and 2-story tar-refining plant at Thirty-ninth St. and Fifty-second Ave., estimated to cost about \$1,000,000, with machinery. The Koppers Co., Union Arcade Bldg., Pittsburgh, Pa., is engineer for the project.

Louisiana

LEESVILLE—The Louisiana Oil Refining Co. and the Caddo Central Oil & Refining Co. are planning for the rebuilding of the portions of their local distributing plants, destroyed by fire, July 23, with loss estimated at about \$25,000.

Maryland

BALTIMORE—The Cooknut Corp., Lexington and Paca Sts., recently organized with a capital of \$500,000 to manufacture lard substitutes and kindred products, is completing plans for the first unit of its proposed new plant, to be located on Canton St. The main works will be 4-story, 80x100 ft., and will be supplemented with two 1-story structures, 28x56 ft., estimated to cost about \$135,000. The plant will be equipped for an initial production of about 60,000 lb. of material per day. W. R. Spruill is president.

BALTIMORE—The Maryland Vegetable Oil Co., Seventh Ave. and Sixteenth St., recently organized with a capital of \$1,000,000, has acquired property at the location noted for the erection of a new plant. Preliminary plans are under way. It is said that the works will cost in excess of \$200,000. The company is headed by Enos S. Stockbridge and Roland H. Brady.

BALTIMORE—The Greenmount Iron Mfg. Co., 833 Greenmount Ave., will soon call for new bids for the erection of the proposed addition to its iron foundry, estimated to cost about \$15,000. Former bids, recently received, have been rejected.

Massachusetts

SOUTHBIDGE—The Optical Abrasive Co., recently organized, has acquired a 3-story building in the Phillipsdale section, heretofore used as grist mill by the Phillips Co., for the establishment of a plant for the manufacture of abrasive products for optical grinding and other precision service. The structure will be remodeled and equipment installed at an early date.

AUBURN—The Bay State Brick & Stone Co., Haverhill, Mass., recently organized, has acquired the plant of the Worcester Brick Co. at West Auburn, which has been idle for about a year past. The company will make a number of improvements and proposes to commence production at an early date. George L. Baldwin, formerly connected with the Worcester company, is an official of the new organization.

Missouri

JOPLIN—The Chanute Smelter Co., Frisco Bldg., has completed plans and will commence construction at once on a new 1-story concentrating plant, 36 x 45 ft., estimated to cost about \$50,000. The structure will be located on the company's property at Baxter Springs, Kan.

SPRINGFIELD—The Springfield Tablet Mfg. Co., 300 North Jefferson St., recently organized with a capital of \$60,000 to manufacture writing tablets and other paper specialties, will install machinery and equipment in a local building. It is proposed to commence production at an early date. H. S. Jewell is president and manager; H. F. Chalfont is secretary and treasurer.

New Jersey

FORDS—The Norvell Chemical Co. is planning for the rebuilding of its local plant, destroyed by fire, July 25, with loss estimated at about \$400,000, including building and machinery. The main works was 3-story, 100 x 200 ft., and the plant gave employment to about 100 persons. The plant was formerly operated by the National Synthetic Co. Donald McKesson is president.

NEWARK—The Tower Mfg. Co., Doramus Ave., manufacturer of chemicals, is planning for the erection of a 1-story addition to its plant, 40 x 143 ft., estimated to cost about \$20,000.

NEWARK—The E. Walsh Co., 127-29 Ogden St., operating a metal working plant, has filed plans for the erection of a 1-story addition, 25 x 60 ft., to be equipped as a japanning shop.

New York

COLLEGE POINT—The I. B. Kleinhart Rubber Co., 725 Broadway, New York, has awarded a contract to the White Construction Co., 95 Madison Ave., for the erection of a new 4-story and basement plant at Fifth Ave. and Eighteenth St., College Point, estimated to cost about \$150,000.

NEW YORK—The Mexican Producing & Refining Co., 136 Liberty St., has acquired a building on Grand Blvd., Pallsades Park, N. J., under lease, for the establishment of a new oil laboratory. The structure will be improved and equipment installed at an early date. Montford S. Orth is president.

Ohio

WOOSTER—The Stellar Refinery Co., 607 Newark Bldg., Wooster, is taking bids for the erection of a new oil refinery at Marne, near Newark, O., estimated to cost about \$300,000 with equipment. The works will consist of a number of buildings, including power house and pumping plant. J. M. Jafflek is secretary.

CLEVELAND—The Sterling Brass Co., 1610-12 St. Clair Ave., has taken new bids on revised plans for the erection of its proposed new 2-story brass foundry and machine shop, 145 x 200 ft., at St. Catherine and East Ninety-third Sts., estimated to cost about \$60,000. S. L. Well is president.

Oklahoma

BRISTOW—The H. F. Wilcox Oil & Gas Co. is perfecting plans for the construction of a new local oil refinery, with initial daily capacity of about 500 bbl.

Oregon

PORTLAND—The Portland Vegetable Oil Mills Co. has construction well under way on its new local plant on site recently acquired, forming the previous works of the Foundation Co. The machinery and equipment is expected to be installed in September and October, having the plant ready for service during the latter month. It is estimated to cost close to \$500,000 with machinery. C. A. Edwards is one of the heads of the company.

Pennsylvania

ALLENTOWN—The plant of the Allen Chemical Co., Fourteenth and Fifteenth Sts., and the Little Lehigh River, has been sold to the Allen Typewriter Co. Chemical manufacture at the plant was discontinued some months ago. The new owner will equip the structure for the manufacture of typewriter parts. James K. Bowen is head.

PHILADELPHIA—E. F. Drew & Co., Inc., Swanson St., near McKean St., manufacturer of oil products, has filed plans for the erection of a 1-story extension at its works.

NEW CASTLE—F. A. Sieberling, formerly head of the Goodyear Tire & Rubber Co., Akron, O., and associates have taken over the local plant of the New Castle Rubber Co. The works will be improved and in the future will be operated under the name of the Lehigh Tire & Rubber Co.; it is proposed to commence production at an early date, providing equipment for an output of about 500 tires and a like number of tubes daily.

Tennessee

MEMPHIS—The Mexican Oil & Refining Co., 510 McCall Bldg., is planning for the purchase of new oil-refining equipment for installation at its plants. J. J. Mundy is engineer.

PARIS—W. G. Adams and associates are planning for the establishment of a new plant on local site for the manufacture of sassafras oil specialties. A company is being organized to carry out the project.

Texas

HOUSTON—W. J. Doyle, industrial land commissioner, Houston Belt & Terminal Co., is developing plans with local interests for the erection of a new sugar mill on a site near Houston, comprising about 60 acres of property. The new mill with machinery is estimated to cost about \$1,250,000. It will be equipped for an initial output of about 600,000 lb. of sugar daily. It is proposed to commence construction at an early date.

DALLAS—The Hercules Brick Co., recently organized, is perfecting plans for the construction of a new plant on a site totaling about 16 acres of land on the Trinity River. The works will be equipped for an output of about 150,000 bricks per day, and are estimated to cost about \$75,000 with machinery. A. B. Salin is manager.

DALLAS—The Trinity Paper Mills, 620 Dallas County State Bank Bldg., are perfecting plans for the construction of a new pulp and paper mill at McKinney, Tex. The company also proposes the erection of a similar mill in the vicinity of Fort Worth, Tex. George F. Lull is president.

Washington

SPOKANE—The Consolidated Diamond Oil & Refining Co., Hutton Bldg., is planning for the construction of a new oil refinery on a site near the city, with initial output of about 500 bbl. per day. The plant is estimated to cost about \$100,000.

West Virginia

STAR CITY—The Star City Glass Co. is planning for the rebuilding of the portion of its works recently destroyed by fire.

Wisconsin

WAUSAU—The Marathon Rubber Products Co. has awarded a contract to the Wisconsin Engineering & Construction Co., Wausau, for the erection of a new local plant to cost about \$15,000, exclusive of equipment.

New Companies

THE ROBERTSON CHEMICAL CO., Money Point, near Portsmouth, Va., has been incorporated with a capital of \$500,000 to manufacture chemicals and chemical byproducts. F. B. Stephenson is president, and C. W. Jones, secretary, both of Norfolk, Va.

THE PENETRO CHEMICAL CO., New York, N. Y., has been incorporated under Delaware laws with capital of \$500,000 to manufacture chemicals and chemical compounds. Arthur W. Britton, 65 Cedar St., represents the company.

THE POSO OIL CO., Los Angeles, Cal., has been incorporated with a capital of \$250,000 to manufacture petroleum products. The incorporators are J. C. Gillham, L. K. Adams, and C. B. Andrews, Merchants National Bank Bldg. The same incorporators have also organized the Poso Kern Oil, with capital of \$250,000 to manufacture petroleum specialties.

THE PABLO HUMUS CO., South Jacksonville, Fla., has been incorporated with a capital of \$10,000 to manufacture fertilizer products. Robert Ranson is president; and J. H. Hickman, vice-president and general manager, both of South Jacksonville.

THE OLYMPIA SPARK PLUG CO., 39 East Schiller St., Chicago, Ill., has been incorporated with a capital of \$5,000 to manufacture spark plugs and kindred specialties. The incorporators are Cornelius C. McMahon, Secor Cunningham, Jr., and Kenneth B. Hawkins.

THE PATUXENT GUANO CO., 407 Vickers Bldg., Baltimore, Md., has been incorporated with a capital of \$75,000 to manufacture fertilizer products. The incorporators are Harry T. Deford and Carroll W. Clark.

THE INSTANT PRODUCTS CORP., Boston, Mass., has been incorporated with a capital of \$100,000, to manufacture chemicals, paints and adhesive compounds, etc. Stanley Morin, 21 Cambridge St., is president and treasurer.

THE AMERICAN GASOLINE CORP., 29 South LaSalle St., Chicago, Ill., has been incorporated with a capital of \$250,000, to manufacture petroleum and petroleum products. The incorporators are Lewis H. Scurlock, W. C. and T. Shelby Black.

THE HAXAGON CHEMICAL CO., 67 Margaretta St., Newark, N. J., has filed notice of organization to manufacture chemicals and chemical byproducts. Frank E. Fitch, 20 Whittlesey Ave., East Orange, N. J., heads the company.

THE WATERPROOF PAPER PRODUCTS CO., Herkimer, N. Y., has been incorporated with a capital of \$50,000, to manufacture paper goods of various kinds. The incorporators are J. R. Hyer, J. Thompson and C. L. Palmer. The company is represented by C. L. Earl, Herkimer.

CHARLES E. CAMPBELL, INC., Elmhurst, L. I., has been incorporated with a capital of \$50,000, to manufacture rubber products. The incorporators are Charles E. Campbell, K. K. Hillabrant and I. G. Wolf, Elmhurst. The company is represented by Baucher & Ganty, 51 Chambers St., New York.

THE HAGAMAN REFINING CORP., Ranger, Tex., has been incorporated with a capital of \$150,000, to manufacture refined petroleum products. The incorporators are M. H. Hagaman and G. A. Clements.

THE ENAMEL PRODUCTS CORP., East Stroudsburg, Pa., has been incorporated with a capital of \$50,000, to manufacture enamelware specialties. Louis Rupprecht, East Stroudsburg, is treasurer.

THE EAST HAMPTON CORK CO., New York, has been incorporated with a capital of \$50,000, to manufacture cork products. The incorporators are A. and R. L. Miller, and S. R. Kaufman. The company is represented by Zodikow & Wieder, 305 Broadway.

THE QUICK KLEAN KEMICAL CO., Worcester, Mass., has been incorporated with a capital of \$10,000, to manufacture chemicals

and chemical byproducts. William Blumenthal is president; Samuel N. Baron, vice-president, and Morris Goldsmith, 37 June St., treasurer.

THE NEVADA-VENTURA OIL SYNDICATE, 422 American Ave., Long Beach, Cal., has filed notice of organization to manufacture petroleum products. The company is headed by D. M. Allen, Charles H. Read and W. H. Young.

THE GRAND RAPIDS METAL PRODUCTS CO., Grand Rapids, Mich., has been incorporated with a capital of \$25,000, to manufacture metal goods. The incorporators are John C. Miller, and Edgar R. Freeman, Grand Rapids.

THE CLERGAS CHEMICAL CORP., Rochester, N. Y., has been incorporated with a capital of \$50,000, to manufacture chemicals and chemical byproducts. The incorporators are R. J. Fisher, C. H. Gunn and J. E. Britton. The company is represented by Sutherland & Dwyer, Insurance Bldg., Rochester.

THE CO-SERVICE OIL CO., Newark, N. J., has been incorporated with a capital of 8,000 shares of stock, no par value, to manufacture oil products. The incorporators are M. E. Russell, E. B. Irons and M. B. Walls, Newark. The company is represented by Benjamin Natal, Court House Square Bldg., Camden, N. J.

THE GROVE CHEMICAL CO., 1200 South Grove St., Irvington, Newark, N. J., has filed notice of organization to manufacture chemicals, lacquers and kindred products. Carl P. Olson, 844 Lyons Ave., Irvington, heads the company.

THE TONKIN FLAKE GRAPHITE CO., New York, N. Y., has been incorporated with a capital of \$150,000, to manufacture refined graphite products. The incorporators are J. J. Tonkin, I. Loewenberg and I. Oliver. The company is represented by Price Brothers, 271 Broadway.

THE ATLANTIC COTTON OIL CO., New York, N. Y., has been incorporated with a capital of \$100,000, to manufacture refined oil products. The incorporators are S. L. Lemmon, J. B. Pruyn and G. H. Salmon. The company is represented by F. J. Knorr, attorney, Albany, N. Y.

THE WAMESIT CHEMICAL CO., Tewksbury, Mass., has been incorporated with a capital of \$100,000, to manufacture chemicals and chemical byproducts. George Stevens is president; and John H. Murphy, 8 Shattick St., Lowell, Mass., treasurer.

THE MICHIGAN REFINING CORP., Detroit, Mich., has been incorporated with a capital of \$100,000, to manufacture petroleum specialties and coal-tar products. The incorporators are Elmer Burell, Henry J. Jebb and Nevin Sturgeon, 1533 Elmhurst Ave.

THE PENNSYLVANIA CHEMICAL & RESEARCH CO., Pittsburgh, Pa., has been incorporated with a nominal capital of \$5,000, to manufacture chemical specialties. R. T. Rosell, Pittsburgh, is treasurer.

THE PUENTE HILLS OIL CO., Los Angeles, Cal., has been incorporated with a capital of \$600,000, to manufacture petroleum products. The incorporators are F. B. Clark, R. L. Brown and R. L. Colby, Chamber of Commerce Bldg., Los Angeles.

THE DU-RITE PRODUCTS CO., New York, N. Y., has been incorporated with a capital of \$25,000, to manufacture varnishes, polishes and kindred products. The incorporators are F. J. McEvoy and J. D. Ohlssen. The company is represented by H. S. Cook, 38 Park Row, New York.

W. A. RARICK, INC., Nanticoke, Pa., has been incorporated under Delaware laws, with capital of \$1,000,000, to manufacture dynamite and other high explosives. The incorporators are Thomas J. Morgan and T. J. Jones, Nanticoke; and William J. Thomas, Mountain Top, Pa. The company is represented by Arley B. Magee, Dover, Del.

THE HARING PAPER CORP., New York, N. Y., has been incorporated under Delaware laws, with capital of \$100,000, to manufacture paper products. Samuel B. Howard, 65 Cedar St., represents the company.

THE ARTESIA OIL CO., Los Angeles, Cal., has been incorporated with a capital of \$500,000 to manufacture petroleum products. The incorporators are J. H. Savage, E. A. Reed and P. E. Keeler, Long Beach, Cal. The company is represented by P. E. Keeler, First National Bank Bldg., Long Beach.

THE PENINSULA TIRE & RUBBER CO., Tampa, Fla., has been incorporated with a capital of \$1,500,000 to manufacture tires and general rubber products. A. B. McMullan is president; S. H. Rogers, Jr., secretary; and H. A. Van Auken, general manager.

Capital Increases, etc.

THE FOLEY PAPER MILLS, Rochester, N. Y., have filed notice of increase in capital from \$25,000 to \$50,000.

THE CAMPBELL MFG. & FOUNDRY CO., Muskegon, Mich., has filed notice of change of name to the Muskegon Castings Co.

THE THOMPSON & NORRIS CO., 212 Concord St., Brooklyn, N. Y., manufacturer of paper products, a New Jersey corporation, has filed notice of increase in capital from \$500,000 to \$2,000,000.

THE RAVENSWOOD GLASS CO., 4247 Lincoln Ave., Chicago, Ill., manufacturer of glass specialties, has filed notice of increase in capital from \$25,000 to \$50,000.

THE DIAMOND COLOR CO., Bloomfield, N. J., has filed a petition in bankruptcy, with liabilities stated at \$30,000. The company operates a plant at 67 Willett St., for the manufacture of chemicals and dyes, etc.

THE ATLANTIC BOTTLE CO., 90 West Broadway, New York, N. Y., manufacturer of glass bottles, has filed notice of increase in capital from \$60,000 to \$300,000.

THE REEDY FOUNDRY CO., 4600 Iowa St., Chicago, Ill., has filed notice of increase in capital from \$75,000 to \$150,000.

THE FRANKLIN OIL & GAS CO., Houston, Tex., has filed notice of change of name to the Cold Test Lubricant Corp.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold its twenty-first annual meeting at St. Louis, Feb. 27 to March 2, 1922.

AMERICAN CHEMICAL SOCIETY, THE SOCIETY OF CHEMICAL INDUSTRY and the American Section of the latter society will hold a joint meeting in New York, Sept. 6 to 10.

AMERICAN GAS ASSOCIATION will hold its third annual convention in the Congress and Auditorium Hotels, Chicago, the week of Nov. 7.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in Lake Placid, N. Y., Sept. 29 and 30, and Oct. 1.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its annual winter meeting at Baltimore, Md., Dec. 6 to 9. Headquarters will be at the Southern Hotel and the sessions will be held in the Engineers' Club.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its fall meeting at Wilkes-Barre, Pa., Sept. 12 to 17.

AMERICAN MINING CONGRESS AND NATIONAL EXPOSITION OF MINES AND MINING EQUIPMENT will hold its twenty-fourth annual convention in the Coliseum, Chicago, Oct. 17 to 22.

AMERICAN PEAT SOCIETY will hold its fifteenth annual convention at the Hotel Commodore, New York City, Sept. 7, 8 and 9.

AMERICAN SOCIETY FOR STEEL TREATING will hold its third annual convention and exhibition Sept. 19 to 24 at Indianapolis.

THE NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SEVENTH) will be held during the week of Sept. 12 in the Eighth Coast Artillery Armory, New York City.

NEW JERSEY CHEMICAL SOCIETY has discontinued meetings for the summer and will resume them in October.

SOCIETY OF CHEMICAL INDUSTRY (BRITISH) at the invitation of the Montreal section will hold its annual meeting in Montreal and other Canadian cities during the week of Aug. 29, 1921. Details will be printed in this magazine from time to time.

SOCIETY OF INDUSTRIAL ENGINEERS will hold its fall meeting at Springfield, Mass., Oct. 5 to 7.

TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its fall convention with the American Pulp and Paper Mill Superintendents' Association, at Washington, Philadelphia, Spring Grove, York, York Haven, Pa., and Wilmington, Del. Oct. 18 to 20.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: Oct. 7—American Chemical Society, regular meeting; Oct. 14—Société de Chimie Industrielle, regular meeting; Oct. 21—Society of Chemical Industry, Grasselli Medal; Nov. 11—American Chemical Society (in charge), Society of Chemical Industry, American Electrochemical Society, Société de Chimie Industrielle, joint meeting; Nov. 18—American Electrochemical Society, regular meeting; Dec. 2—Society of Chemical Industry, regular meeting; Dec. 9—American Chemical Society, regular meeting.

Number 7

For the Edification of Readers and Advertisers

MAY we have your indulgence while we talk shop for a moment? Contrary to the impression of an earlier day, the editorial conduct of a modern technical magazine is not a chance feature of the publishing business. On the contrary it is the result of a deliberate policy that forms, or should form, the foundation for the whole superstructure of service which is the magazine's *raison d'être*. Now a modern magazine serves three groups of people: the readers, the advertisers, and the publishers. All contribute to the success of the undertaking, and each must profit by what he puts into it or he will not continue to invest. The reader must have a sense of value received for the subscription price; the advertiser must feel assured of the buying power of the circulation; and the publisher must realize a fair return on his investment which is the recognized reward for his enterprise and risk. Let any one of these elements fail to realize a reasonable degree of satisfaction over an extended period of time, and the whole structure will fall to the ground.

Perhaps it is not overstating the case to say that not only will editorial competence assure the reader a reliable and useful professional tool, but that editorial integrity will also constitute a basic guarantee of the magazine's value to the advertiser. In other words, high standards of editorial ethics and practice will react to the benefit of not only the reader but of the advertiser as well, and ultimately of the publisher. It is of course assumed that equally high standards of business practice are recognized; but for the moment we are emphasizing the value of editorial integrity, because it is in that department that a surrender to low standards would work fundamental harm and perhaps ultimately ruin the publication through loss of confidence and prestige.

With this brief preamble we offer for the edification of our subscribers and advertisers the standards of editorial practice recently adopted by the Editorial Conference of the New York Business Papers, Inc., of which CHEMICAL & METALLURGICAL ENGINEERING is a member. Certainly they represent the best thinking of the day on the part of an important group of editors, each of whom has pledged himself

1. To consider first the interests of the subscriber.
2. To work for truth and honesty in all departments of his publication.
3. To publish in an impartial way, free from personal opinion, the news of the industry in which his paper circulates.
4. To disregard advertising considerations in the editorial conduct of his paper.
5. To be a leader of thought in his editorial columns and make his criticisms constructive, with the object of bringing his industry to higher levels of thought and practice and to a greater measure of public service.
6. To support in his columns such worthy measures of

public interest as their importance justifies and the space available permits.

7. To give proper credit for articles taken from other publications, and to avoid unfair practices in competition with them.

It will be noted that the interest of the subscriber, the reader, is the editor's first consideration. This is quite logical, for if the editor cannot produce a magazine that readers will buy continuously and in large volume, it will have no value as an advertising medium and will yield no revenue to the publisher. The magazine is made primarily for the reader because if his interest and loyal support can be maintained he becomes a receptive and impressionable audience for the advertiser. Confidence thus gained editorially is automatically converted into a business asset.

Probably none of the other standards enumerated above requires elucidation unless it be No. 4. It is a difficult standard to phrase; but it is intended to express editorial independence of that baneful influence which was more characteristic of the early days of business publishing, but which is still sometimes exerted on the editorial department by advertisers. The purpose of that influence is variable. Sometimes it is merely to gain additional publicity through the text pages. Occasionally it takes the form of propaganda, more or less insidious and difficult to recognize. But its most pernicious manifestation is an attempt to influence editorial policy or to suppress publication of articles, using as a club the threat to withdraw advertising patronage.

Of course it is the sincerest recognition of the value of the text pages that advertisers should want "reading notices" and all that category of trade items published therein; but the editor is not justified in publishing them unless they interest or instruct the reader. Certainly it is a mistaken point of view to regard the publication of such items as an advertising perquisite. And as for allowing editorial policy or purpose to be swayed by pressure from an advertiser, second thought will make it very clear that such a course would lead to editorial and business practices of the most pernicious character, bordering on bribery and blackmail if not actually descending to them. The very thought is abhorrent and quite inconsistent with the fundamental truth of science and honesty of engineering. Editorial integrity should not only be expected but demanded by advertisers.

As a whole we regard the standards of the New York business paper editors with approval and satisfaction and subscribe to them with pleasure, feeling that they will aid in bringing the whole field of business and technical publishing "to higher levels of thought and practice and to a greater measure of public service." Publisher, advertiser and reader could ask no more; and in devoting his primary attention to the reader's interests the editor feels that he is contributing directly to the consummation of this desirable state of affairs.

Who Knows About Internal Strain?

A PAPER by JAMES E. HOWARD, reprinted on another page of this issue, brings to mind the need of investigations in a neglected field, but necessary before the mechanical engineer and designer can make the best and most economical use of the quality materials furnished by modern metallurgy. We refer to work immediately directed at the everyday problems of stresses and strains; questions which arise from the service requirements of steel and the best methods to meet them. Such things are most essential for intelligent and scientific design, and there ought to be a ready fund of information about them; but very little is available and less is being presented. Efforts of metallurgists are largely concentrated upon the production of uniform metal of superior physical properties; they leave it almost wholly to the user to determine the kind of service these steels shall enter, and doubtless in most cases they are unfamiliar with many matters pertaining to the actual problems which the uses of steel's present. The user, on the other hand, rests secure in the thought that if a certain part shows a high percentage of failures, it can be "redesigned," or made of another metal selected from the almost bewildering number now available.

Engineers and scientists have really been progressing but slowly into the general problem of distribution of stress in a resisting solid. HOOKE enunciated his law that the "power of a spring is proportional to its stretching" in 1676, but an arithmetical figure for this proportion was not forthcoming until 1807 when YOUNG described the physical constant now known as Young's modulus. POISSON, twenty years later, established the ratio between lateral contraction and longitudinal extension. The problem of a shaft in torsion was not solved by SAINT VENANT until 1855, and about that

same time the simplified beam formula $M = \frac{pI}{E}$ came into general currency. Since that time there has been little more than the production of a maze of figures, symbols and equations based on Hooke's and Poisson's laws, attempting to determine the stress distribution in rectangular beams without using several slightly erroneous but simplifying assumptions, and in flat or curved plates. When the beam becomes a column, or is a built beam, or the plate has a few holes or notches, either internal or external, then even this mass of figures, not understandable to any except expert mathematicians, becomes useless, and the engineer must rely upon his good friends Common Sense and Factor of Safety.

Prof. COKER has but recently taken a long step forward by constructing models of glass, celluloid or other transparent amorphous substances, and has been able to exhibit visibly the distribution of stress by the production of beautiful colored patterns due to double refraction of transmitted polarized light. He finds, for instance, that the distribution of stress at a contact surface is all important in that region. Its distribution, easily found by these models, is in such cases of much more importance than its exact magnitude, found laboriously, if at all, by complicated mathematics—for by proper experimentation methods may be devised to remove dangerous concentrations. Once removed by correct design, who cares how big they might have been?

Something has been done in studying the mechanism of failure. LÜDER (in 1859) noticed that plates or rods loaded slightly higher than the elastic limit developed geometric surface markings, indicating regions within which a shearing deformation had taken place. Experiments of this kind have been a very useful guide for workers in the theory of elasticity, and in indicating where dangerous stress intensities will develop in intricate shapes. Much more valuable information has been forthcoming in the last few years following the recognition of the fact that metals are crystalline aggregates, and by the microscopic study of deformation, normally caused by slip among cleavage planes in the crystal itself. This at least has given us a good idea of the way to harden and strengthen metal and just what happens when a metal is overstrained.

However, these studies are of conditions which exist at very high loads, loads which are much beyond those an engineer would like to impose on his structure. What he expects of the metallurgist is homogeneous metal, free from internal notches and invisible defects. The metallurgist must ever strive to approach this ideal. Nor can he remain entirely indifferent to questions which merit the designer's most careful attention: How much less is the resistance to shear on a plane which already bears a certain tension? How much tension will metal endure when it is prevented by sidewise constraint from contracting laterally? What is the relation between the stresses set up in a piece by a load at rest, or the same load dropped one foot? Do the same forces come into play in resisting indentation and cutting?

Studies of minute movements in the interior of opaque bodies are bound to be very difficult; but that is no reason why they should be dodged.

Patent Litigation of Unusual Interest

SELDOM has a case in the courts attracted the interest of the chemical industry in so great measure as has the litigation over the patents for synthetic phenolic resins. As a result of a second long-drawn-out legal contest, three more of the original patents of Dr. BAEKELAND have just been declared valid and infringed. In the case under trial the patents were those relating to the molding and application of the synthetic resinous material, while it will be recalled that in the previous suit the so-called varnish and solution patents were those in question. The present suit was brought against a user rather than the manufacturer of the synthetic gum, although, as pointed out in the Court's opinion, the trial largely hinged on a consideration of the nature of the synthetic product itself. Naturally the manufacturer of the infringed product was deeply interested in the success or failure of his customer's case and stood squarely behind the defendant in all discussion relating to questions of patentability.

Judge CHATFIELD'S opinion is an exact and comprehensive survey, which is of historical importance both from the technological and purely legal viewpoints. Elsewhere in this issue a few pertinent paragraphs have been abstracted from the opinion, but the character of the document is such as to warrant a much more extended study by all who are interested in the scientific and commercial aspects of this important chemical industry.

We have previously referred to the contest as one of

long duration and perhaps we have been too critical of the processes of law and justice. Many cases, especially under the older régime of patent litigation, have extended over periods of many years, so that in this particular instance action may not have been unusually slow. The complaint was filed Sept. 18, 1917, but it was not until March 31, 1919, that the case could be brought to trial. The taking of testimony extended over many weeks and the final arguments were heard on June 22, 1919. Two years then elapsed, during which the presiding judge prepared his opinion and rendered his decision. To some this may seem excessive and sufficient even to call for the use of a catalyst or organic accelerator. When one considers, however, the great mass of testimony involved and its technical and scientific nature, it is evident that much careful, time-consuming study is required.

Turning our attention again to the Court's opinion, we are immediately struck with an interesting and logical comparison. Judge CHATFIELD declares that "if artificial diamonds could be produced, no one could claim as invention the substance already known as diamonds, and if the imitation could not be told from the original, no inventor could control all the material of that nature, whether produced naturally or artificially. But the inventor who does finally invent a process for manufacturing genuine diamonds, by artificial means, will be able to claim as an inventive product that material which any one is producing by the steps covered by his invention, if he obtains a patent therefor.

"Thus in all the BAEKELAND patents, the product which is sought to be patented is not the material, which can only be identified as an infusible and insoluble condensation product of phenol and formaldehyde. But BAEKELAND can validly claim a new product, which is produced by exactly the steps which he has described and which makes use of the ideas which he recognized and claimed as invention in arriving at a result which may then contain or even be substantially composed of a substance that of itself is not patentable, provided it can be shown that it was manufactured in a way not taught by the prior art, and can be identified by the original methods or steps in the process."

Newspaper

Electrochemistry

IT DOES beat all what we read in the newspapers! Here is a gem of wisdom sent in by our electrochemical friend who led us into temptation that landed us in trouble about rhodium when we failed to observe that there is also a plant of that name. The item is taken from the *New York Sun* of Aug. 9, and was printed under the caption Kitchen Economics: "If a needle is held between the lips while peeling onions, water will be kept from the eyes, and it also prevents smarting." What kind of galvanic action does it set up? Was it meant for girls with metallic lips? We have always felt that there was a considerable electric charge in some lip tissue, but we have never undertaken research with cooks or scullery maids. On the other hand, one doesn't have to be a cook or a scullion to peel onions. We have done it ourselves, but in all our long, modest life we have not been given to understand that our lips were especially charged with electrons. Chemists working with mercaptans might make a note of this alleged phenomenon of the needle—and then they might as well forget it again for all the good it is likely to do them.

The Ups and Downs of Steel

JULY, 1921, will probably go down in history as the month of lowest production of steel in these modern times. Production of ingots in July was at the rate of about 11,000,000 gross tons a year, or about 21 per cent of actual capacity, the lowest rate being struck at the middle of the month, since when there has been an improvement, one that will probably continue indefinitely, though perhaps at a slow rate. The July rate was approximately one-fourth the average rate maintained during the first nine months of 1920. Approximately the same rate was struck for a short time after the panic of October, 1907, but for production in a year as little as 11,000,000 tons one must go back to 1900. Production in the best year before the war was almost three times as great.

In contrast with this very low rate in steel production there is the fact that the railroads have been and are hauling a little more freight, measured by ton-miles, than in their best year before the war, that having been the fiscal year ended June 30, 1913, when the revenue ton-miles were 301 billion.

One is reminded that old descriptions of the steel industry are more apposite than ever. The late ANDREW CARNEGIE coined the phrase "prince or pauper" industry. The late JAMES M. SWANK had previously referred to "chill or fever" and "feast or famine." That is, the producers of steel are either princes or paupers, buyers have either a fever or a chill, orders for steel suggest either a feast or a famine.

Being in large measure a construction material, steel exhibits variations in demand according to the volume of construction. Men eat bread and wear clothes every day, but only occasionally build a house, a factory or a power plant. Other factors, however, magnify the peaks and troughs in the demand upon the steel mills. Between the steel mills and the ultimate consumption there is a volume of material, including rolled steel products and various wares made from steel, in the hands of manufacturing consumers, wholesalers and retailers. When business is active this is a stream, but when business becomes bad the stream becomes a reservoir, which has to empty itself. Manufacturing consumers whose policy had been to keep a three or six weeks' supply of steel on hand liquidate their stocks, intending for a time to depend on carload shipments.

During the war there were fears that the steel industry was getting oversized for a normal peace-time consumption. Such fears may have been right or they may have been wrong, but that has nothing to do with the present condition, for the reason that the increase in capacity since 1914 has been about 50 per cent, so that a 20 per cent operation of today's capacity means the same tonnage as would have required 30 per cent of the capacity before the war.

Meanwhile the wear and tear of the machinery, implements and structures made of steel goes on, and men's vision grows as to the bridges, buildings, power plants and other things they will be able to employ usefully in future. Eventually the steel trade will "come back." Just now, as the reservoir between mill and ultimate consumption is being depleted of steel and manufactures of steel, the mill demand is working its way up to a normal relation to general business. Stocks of steel and of manufactures of steel have been in process of liquidation.

Readers' Views and Comments

The Microscope; Its Design, Construction and Applications

To the Editor of Chemical & Metallurgical Engineering

SIR:—Under "Book Reviews" in your issue of June 29, 1921, I find a review of the very excellent symposium on "The Microscope; Its Design, Construction and Applications" held during 1920 by the Faraday Society.

I find that Dr. Boylston, in quoting the summary of an investigation by Prof. Benedicks of the new Reichert metallographic outfit, which was largely designed by me, leaves out an important sentence reading as follows: "It was found to produce excellent results at the very highest magnifications." Benedicks considers this sentence as the main result of his investigation and mentions the other points cited by Boylston simply as "points of a more general character," since six out of the seven points mentioned do not refer to the apparatus under investigation, but to the subject in general.

Prof. Benedicks has published several other papers on the same apparatus, in which he goes more into details of the results of his investigations than he did in his short paper contributed to the Faraday Society symposium.

The success of this excellent symposium is undoubtedly due to the untiring efforts of Sir Robert Hadfield, and I was glad to accept his invitation to contribute a short paper to the same symposium.

New York City.

Note on Alloying Tellurium With Some White Metals

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to the paper on the above subject by J. H. Ransom and C. O. Thieme on page 102 of the July 20 issue of your journal, there should be little difficulty in proving that tellurides of the white metals are formed instead of leaving the matter in the "probable" class, as is done in the authors' last paragraph. Indeed, I have no doubt that the authors actually did obtain tellurides, since in my own work on this subject more than fifteen years ago I invariably obtained them. This could be proved by the fact that the lumps which formed over the metal gave hydrogen telluride when treated with a weak acid.

The "glow" which the authors noted as taking place when the tellurium was immersed in the alloys and metals which they were using was due to the chemical action resulting in the formation of a telluride. Telluride of aluminum is a particularly interesting body, because it not only gives hydrogen telluride when treated with weak acids but even when treated with water only, making it the most convenient reagent that I know of for generating this gas. Aluminum telluride is itself easily made by melting aluminum in a scorifier or porcelain crucible and dropping tellurium into it.

Magnesium telluride is also an interesting compound and is made the same way, but care should be taken not to superheat the magnesium above its melting point or

an explosion takes place and the magnesium telluride is found mainly on the walls and roof of the muffle. I always preferred to wear a mask and heavy goggles when making magnesium telluride, for the reaction is violent and comes in the hazardous class.

The selenides may be prepared in the same manner. It should perhaps be recalled to mind here that anyone experimenting on producing hydrogen selenide or hydrogen telluride should be most careful about inhaling either of the gases. To most persons they seem far more poisonous than sulphuretted hydrogen. As to hydrogen selenide, may I recall the classic quotation that "its discoverer, Berzelius, had his olfactory nerves paralyzed for six months by inhaling a bubble of the pure gas"? Judging from my own experiences, in the one whiff that he must have caught before paralysis set in he had enough olfactory sensations to have lasted him longer than the six months specified.

New York City.

DONALD M. LIDDELL.

Determining Factors for the Life of a Pneumatic Tire

To the Editor of Chemical & Metallurgical Engineering

SIR:—I trust it is permissible to call attention to a few corrections that should be made in the article on pneumatic tires, page 153. The subject matter is more mechanical than chemical, but as long as it was seen fit to publish this text, it is only proper that certain misleading ideas should be corrected in order that the readers of CHEM. & MET. should get complete facts on this great industry.

First, there are three types of pneumatic tires—square-woven fabric, thread fabric (so-called cord) and rope cord.

Second, use of cord fabric reduces the internal friction and heat developed in woven fabric tires, but it does not minimize these faults. The rope cord tire is built so there is a layer of gum rubber surrounding each of the ropes of the carcass. There is no rubbing between ropes and therefore this class of tire will not develop as much heat under the most severe road conditions as either of the two other types. In short, the rope cord tire practically reaches the ideal condition mentioned in the article.

Third, the rope cord tire is being manufactured at about 30 to 50 per cent less cost than cord fabric tires of similar size. The rope cord tire surpasses the fabric and ordinary "cord" tire in resiliency, absence of internal heat, gasoline mileage, bursting strength and cost of manufacture. The time is not far distant when the woven fabric tire and the cord fabric tire will both find themselves supplanted by the rope cord tire.

Fourth, a breaker strip functions to distribute the pressure occasioned by running over a stone or other angular projection so that the carcass of the tire will not receive a blow concentrated on a small area.

Fifth, iron cores are not used in building rope cord tires. The process is simple and eliminates much of the trouble from overflow, wrinkling of plies and breakers, bead weakness and other mechanical difficulties.

Arlington, N. J.

O. W. PICKERING.

British Chemical Industry

FROM OUR LONDON CORRESPONDENT

LONDON, July 21, 1921.

IT was long considered axiomatic that Manchester was the ultimate pulse for trade movements and at the present moment the distinctly improved tone and increased volume of business and employment in the cotton trade are considered to foreshadow a steady revival in the chemical industry and in the trade of the country. Important orders from America and India have contributed to this, but the absence of cheap coal is still a great handicap, as Belgian and German competition are likely to keep the majority of blast furnaces out of action for some time. Coal also remains the obstacle to a revival in the glass, pottery and similar trades, but the outlook in the chemical and dyestuff industries generally is better than for some time past, and although the immediate demand is small, it is known that stocks are now very low in most cases.

DELEGATES TO SOCIETY OF CHEMICAL INDUSTRY'S AMERICAN MEETING

Excluding the ladies of the party, the total number of members who have so far reserved passages is twenty or twenty-five. Sir William Pope, the president; Dr. J. P. Longstaff, the secretary, and E. V. Evans, honorary treasurer and chief chemist of the South Metropolitan Gas Co., are the official members of the party, which also includes the following, among others:

E. A. Alliot, of Manlove, Alliot & Co., filter press and mechanical plant specialists; F. W. Attack, well known in the dye industry, editor of the "Chemists' Year Book" and a leader in the movement toward compilation of compendia in English similar to Beilstein, etc.; R. H. Clayton, of the Manchester Oxide Co.; F. W. Gamble, of Allen & Hanbury, Ltd., manufacturer of pharmaceutical products; C. S. Garland, a vice-president of the society and chairman of Lighting Trades, Ltd., a subsidiary company to Nobel Industries; Captain C. J. Goodwin, honorary treasurer of the Chemical Industry Club, London, and the official delegate of the chemical engineering group of the society, a partner in Oscar Guttman & Sons, consulting chemical engineers; W. Heap, L. A. Jordan, chemical engineer to the British Xylonite Co., Ltd.; J. MacWilliam, consulting metallurgist, Sheffield; J. Reid, of the Caldercruix Paper Mills, Airdrie, Scotland.

So far no visitors are announced from France, but it is always possible that there may be a last-minute rush from this country and in some cases, such as for instance, Emile Mond, business engagements prevent members from participating in the full programme and they may sail at a later date. P. le Good, the advertising manager, is also of the party and it is understood that a stall at the Exposition of Chemical Industries has been reserved by the society, at which full information regarding its publications and other activities will be available.

PARLIAMENTARY AND INDUSTRIAL NOTES

The committee stage of the key industries bill was something of a farce and perhaps it was just as well that the "guillotine" prevented further futile discussion. The bill is to come into operation on Sept. 30 and as regards "dumping" will not apply to any

British dominion. As regards depreciated exchanges it will not now apply to cases where the currency concerned is less than 33½ per cent below the sterling par value.

Very encouraging reports have been received unofficially regarding the progress of the Claude process of nitrogen fixation and the various groups of experts who have seen demonstrations consider it to be commercially far superior to the Haber process. Considerable improvements have been effected in the process as disclosed by the patents so far published, particularly as regards the Claude method of hydrogen manufacture and the type of solvent used for same. Catalysis is said to proceed smoothly even in the presence of relatively considerable quantities of carbon monoxide.

In this connection, the discovery by the Catalpo interests (British Patent 164,808) that colloidal clay will synthesize ammonia at 450 deg. C. and at atmospheric pressure is of peculiar interest. Water vapor, it is stated, can be used instead of hydrogen and the use of this new catalyst is also advocated for hydrogenations and for the manufacture of acetaldehyde and formaldehyde.

LEADING CHEMICAL CORPORATIONS PASS DIVIDENDS

One result of the recent depression in trade, industrial unrest and Continental competition has been the passing of dividends in the case of firms like Nobel Industries and the British Dyestuffs Corporation. In the case of Nobel Industries considerable courage must have been displayed by the directors, for in spite of the fact that the profits for the past year were on a par with those earned in the previous two years, it was considered wise to keep all cash resources liquid. In such cases the directors themselves are usually holders of large blocks of shares and are therefore hit more heavily than the other shareholders and it is felt that foresight and caution of this kind will meet with its due reward later on. The case of the British Dyestuffs Corporation looks rather more serious, as it is the interim dividend on the preference shares that has been passed, but recent events and the changes in the management referred to in my previous letters have probably contributed to the present difficult position. As was generally expected, the report of the profiteering committee exonerated the dyestuffs industry but at the same time recommended caution and watchfulness in the future.

GENERAL NOTES

The annual meeting of the Association of British Chemical Manufacturers was a spectacular success, but doubt is expressed as to whether the actual work done apart from organization really corresponds to the claims made. This applies equally to the newly formed Association of Chemical Plant Manufacturers and considerable time will probably elapse before the notorious inertia of the British chemical industry can be finally overcome and really useful results attained. The annual report of the Alkali Works Inspectors follows traditional lines and its contents confirm the above opinion to some extent. Molybdenum metal is attracting interest at the moment and very large contracts could be placed provided supplies were obtainable at well under \$200 per ton.

Action of Lime in Magnesium Oxychloride Cements

Detailed Study and Discussion of the Action of Lime Impurities Occurring in Magnesite on Magnesium Oxychloride Cements—Methods of Determining and Differentiating Active From Inert Lime

BY MAX Y. SEATON, CLAUDE R. HILL AND L. C. STEWART

PLASTIC calcined magnesite differs from dead-burned or metallurgical magnesite in being burned at a much lower temperature. Dead-burned magnesite, in which periclase formation has gone on to a greater or less extent, does not react with magnesium chloride. The material now in use by the oxychloride industries is prepared by calcining any reasonably pure natural magnesite, such as occurs in Greece, in Venezuela, in Washington and in California, to a temperature of 700 to 1,100 deg. C. in shaft, Scott or rotary kilns. The commercial product is a white or light-colored powder, containing ordinarily 75-85 per cent MgO, 5-10 per cent CO₂ and H₂O, 1-2 per cent R₂O₃, 5-7 per cent SiO₂ and 3-6 per cent CaO.

The testing of plastic calcined magnesite has long been a serious problem to users of this material. An attempt has been made to regulate quality by specifying a definite chemical analysis which the material must meet to be accepted. Unfortunately, it has been found that poor as well as good calcined magnesite will meet these chemical specifications. The industry in general is coming to believe that a specification for this product should be written on the basis of physical tests only, with entire elimination of chemical analysis. The physical tests ordinarily recommended are those for fineness of the calcined magnesite, and for strength, constancy of volume, setting time, and resistance to water of the finished cement. Tests of this nature unquestionably furnish valuable information as to the quality in calcined magnesite. It is interesting to compare such test results with the results of chemical analysis and particularly to search for special analytical determinations which might throw light on the question of quality before totally abandoning the use of chemical tests. One determination which is frequently stated as being of particular value is that of the amount of lime in the calcined magnesite, and some investigation of the meaning of this determination seems warranted.

INERT AND ACTIVE LIME

From the start some distinction as to the form in which the lime occurs must be made. In many oxychloride cement mixes marble dust or limestone powder is deliberately used as an aggregate without exerting any harmful influence on the properties of the cement. Such forms of calcium carbonate act merely as inert material, their effect on the character of the cement being roughly equivalent to that of a fine sand or ground silica of equal fineness. The report of the presence of a definite amount of lime in a calcined magnesite is accordingly meaningless unless the form in which it occurs be also specified. It is well established that addition of calcium oxide or hydroxide to an oxychloride mix markedly diminishes its strength. Lime in this form or, more exactly, any form of lime which exerts an injurious effect on the quality of an oxychloride can

well be designated as "active lime," and it would be expected that a determination of the content of lime of this character would be of considerable value.

The reduction in strength caused by addition of lime to oxychloride cements has been mentioned by several writers. Quantitative data are quoted by Rourke.¹ A tabulation of his results is given in Table I, where the effect of lime addition on the cement formed from two different magnesites is shown.

A similar set of determinations in which strengths at both seven days and thirty days were investigated is shown in Table II. The very marked decrease in strength should be carefully noted.

TABLE I. EFFECT OF LIME CONTENT, AS DETERMINED BY ADDITION OF LIME

No. Lime Added	3.70%	Tensile Strength, Lb. per Sq. In.	0.67%
1	329	364	486
2	328	320	470
			826
			653

TABLE II. EFFECT OF ADDITION OF Ca(OH)₂ TO CALCINED MAGNESITE

1 part magnesite, 2 silex, 5 sand, by weight.		22 deg. Bé.	MgCl ₂
		Tensile Strength, Lb. per Sq. In.	
Per Cent Ca(OH) ₂		7 Days	30 Days
0		490	882
1		397	562
3		347	473
6		150	247
10		207	230

Several different possibilities for the determination of active lime may be considered. One such method is indicated by the work of Duschak.² This method rests on the difference in solubility between calcium and magnesium hydrates in water. Duschak points out that if a sample of calcined magnesite be agitated with water for some time, the alkalinity of the water will correspond to the content of calcium oxide present in the original sample. The procedure which he finally adopted was the leaching of the sample with water by standing over night, followed by filtration and by titration with standard acid, using phenolphthalein indicator, the next morning. If the magnesite was burned at a temperature exceeding 1,000 deg. C., the lime was slowly and incompletely dissolved, but magnesites burned at lower temperatures gave good results. The method is simple and rapid as far as working time is concerned. It has been carefully investigated and the effect of various modifications in the procedure studied. In the series of experiments following, 2 g. of the calcined magnesite under investigation was added to 300 c.c. of CO₂-free water and agitated on a shaking machine for various periods of time and under varying conditions.

The rate at which lime is extracted is of course of importance. Table III gives some data on this subject.

¹University of Wisconsin Bulletin 879.

²CHEM. & MET. ENG., vol. 23, p. 628.

It should be noted that when continuous agitation is employed a time very much shorter than that used by Duschak is apparently sufficient to completely remove the lime. Longer agitation, in fact, appears to reduce slightly the alkalinity of the solution. The effect of temperature on the determinations is indicated from the comparative determinations at four hours' agitation. This factor exerts apparently only a minor effect on the amount of free lime found.

TABLE III. EFFECT OF TIME OF AGITATION ON PER CENT CaO IN WATER SOLUTION

Time	Magnesite No. 12. Temperature 18 deg. C.	
	Per Cent CaO From Phenolphthalein	Per Cent CaO From Alkalinity—Methyl Orange
0.25 hr.	1.49	1.57
0.50 hr.	1.47	1.55
1.0 hr.	1.43	1.48
2.0 hr.	1.49	1.55
4.0 hr.	1.53	1.63 (20° C.)
	1.41	1.52 (87° C.)
	1.30	1.40 (3° C.)
8.0 hr.	1.34	1.47
16.0 hr.	1.25	1.39
24.0 hr.	1.11	1.24
2 days	1.30	1.40
4 days	1.21	1.36
8 days	1.26	1.42
15 days	1.47	1.54

The reduction in alkalinity on long agitation can possibly be accounted for by action of the calcium hydrate solution on the glass of the bottles. That such an effect does exist is shown in Table IV, where the titrations of dilute calcium hydroxide solutions after varying periods of shaking are given. This effect, too, is seen not to be a major one, but is of about the order of the reduction in alkalinity shown in the previous table.

TABLE IV. EFFECT OF GLASS BOTTLE ON ALKALINITY OF Ca(OH)₂ SOLUTION

Time Shaken, Hours	Titrated to Phenolphthalein End Point C.e. N/10 Acid	
	Without Filtration	After Filtering
0	5.04	5.04
4	4.90	4.62
8	4.88	4.66
24	4.88	4.66
48	4.82	4.68

Maximum difference is equivalent to 0.18 per cent CaO, figured on basis of usual determination.

Question may be raised as to the meaning of the alkalinity titration—that is, as to whether all of the alkalinity is due to lime. Duschak has given some data on this point. Additional figures are given in Table V, in which a comparison of the amount of calcium oxide

TABLE V. DETERMINATIONS OF ACTIVE LIME BY MODIFICATIONS OF WATER METHOD

Magnesite	Per Cent CaO by Alkalinity of H ₂ O		Per Cent CaO by Precipitation as Oxalate	Per Cent CaO by Alkalinity of 5 per Cent NaCl	
	Phth.	M.O.		Phth.	M.O.
1	0.34	0.45	0.23	0.95	1.53
2	0.37	0.43	0.38	0.83	1.15
3	0.29	0.39	0.27	1.19	1.61
4	0.43	0.50	0.44	0.92	1.20
5	0.72	0.80	0.76	1.04	1.23
6	0.72	0.78	0.71	1.17	1.26
7	1.03	1.07	1.14	1.26	1.40
8	1.34	1.43	1.47	1.70	1.85

as determined by titration of the alkalinity of the solution and calcium oxide determined by precipitation of the lime as oxalate is given. It is seen at once that the alkalinity may be taken as a measure of the calcium content of the solution. In this same table the effect of addition of sodium chloride to the water is shown. The results in this case are very much higher than when no sodium chloride is used. In particular the quite wide difference between the methyl orange and

the phenolphthalein titrations on the sodium chloride solutions from certain magnesites should be observed. It is probable that this is due to the increased solubility of calcium carbonate in the presence of sodium chloride.

ACTION ON MAGNESIUM CHLORIDE SOLUTION

There seems little doubt that the method described above will indicate the amount of calcium oxide or of calcium hydroxide actually present. Such lime, which may be designated as "free lime," does not necessarily comprise the total of the so-called active lime in the calcined magnesite. For example, the phenomenon of a striking reduction in strength of oxychloride cements on addition of small quantities of precipitated calcium carbonate has been frequently observed. Such calcium carbonate will show essentially zero alkalinity when agitated with water, yet its effect on the strength of oxychloride cements is almost as great as that of calcium hydroxide itself. It is felt, too, that an analytical method which approaches somewhat more closely to the conditions existing during the formation of the magnesium oxychlorides would be less open to criticism than the method given above. The solution used in mixing oxychloride cement is not water, but is a solution of magnesium chloride. Calcium oxide or hydroxide will of course react with such a solution with the precipitation of magnesium hydroxide and the introduction of calcium chloride into the reaction mixture. The literature indicates that certain forms of calcium carbonate will react in much the same way.

Some study of an analytical method in which leaching with magnesium chloride solutions is employed was accordingly undertaken. The method finally adopted was the agitation of 2.5 g. of calcined magnesite with 300 c.c. of 0.75 per cent magnesium chloride solution. After a specified period of agitation, the solution is made up to 500 c.c., filtered, and an aliquot part, usually 100 c.c., taken for analysis. Calcium is determined in the solution by double precipitation as oxalate, using the precautions which are always necessary when calcium is to be determined in the presence of a large quantity of magnesium. Use of such a method divides

TABLE VI. ACTIVE, RESIDUAL AND TOTAL LIME IN CALCINED MAGNESITE

Magnesite No.	Active CaO MgCl ₂ Method	CaO in Residue	Sum	Total CaO on Separate Sample
K	1.53	2.82	4.35	4.34
L	2.82	0.81	3.63	3.89

the total lime present in the magnesite into two portions, as shown by Table VI. This table indicates the lack of relationship between total calcium oxide and active calcium oxide and indicates, too, the possible accuracy of the analytical determination involved.

The rate at which the active calcium present reacts with the magnesium chloride must be studied before the time of agitation can be definitely set. Some data on this subject are given in Table VII which shows that twenty-four hours' agitation is sufficient to remove by far the majority of the lime which will react, although some small reaction occurs even after this period.

On the basis of the data so far submitted, three methods for determination of active lime may be considered.

Agitation with water and determination of alkalinity with phenolphthalein indicator.

Agitation with 5 per cent sodium chloride solution and determination of alkalinity with methyl orange indicator.

TABLE VII. EFFECT OF TIME OF SHAKING ON PER CENT CaO BY MgCl₂ METHOD

Magnesite No. 13			
Time	Per Cent CaO	Time	Per Cent CaO
2 hr.	2.80	2 days	3.49
4 hr.	3.02	4 days	3.54
8 hr.	3.19	8 days	3.93
16 hr.	3.47	15 days	3.67
24 hr.	3.45		

Agitation with magnesium chloride solution and determination of calcium chloride in the solution.

Comparison of the results obtained from the application of these three methods is given in Table VIII.

TABLE VIII. COMPARISON OF METHODS FOR ACTIVE CaO

MgO No.	Alk. in H ₂ O Phth. Ind. Method 1.	Alk. in 5% NaCl M.O. Ind. Method 2.	MgCl ₂ Method Method 3.	Ratio 3:1	Ratio 3:2
1	0.34	1.53	1.54	4.53	1.02
2	0.37	1.15	2.00	5.41	1.74
3	0.29	1.61	1.59	5.48	0.99
4	0.43	1.20	1.88	4.37	1.57
5	0.72	1.23	2.30	3.19	1.87
6	0.72	1.26	3.35	4.65	2.66
7	1.03	1.40	3.28	3.18	2.34
8	1.34	1.85	4.00	2.95	2.16

It is seen at once that there is apparently no relation between the values thus obtained on the eight different calcined magnesites investigated. The ratio between the values is far from constant. Methods 2 and 3 are closer than methods 1 and 3, but even here the variation in ratio is very great.

DETERMINATION OF CALCIUM CHLORIDE PRODUCED IN CEMENT

The real test of the value of any such methods is, of course, their comparison with conditions existing during formation of the oxychloride cement. As has been indicated, a method involving treatment with magnesium chloride would be expected to be closer to practice than one employing leaching by water only. For a further study small amounts of oxychloride cement were prepared from three different calcined magnesites, using the strength and amount of magnesium chloride solutions ordinarily used in practice. These cements were allowed to set for varying periods. They were then powdered and agitated for a considerable time with neutral alcohol. It would be expected that this procedure would remove the majority of the calcium chloride formed by reaction of the active lime with magnesium chloride, although there is, of course, a possibility of the formation of small quantities of calcium oxychloride which might not be decomposed under such conditions. The alcoholic solution was then filtered and calcium determined in it, the results being calculated back to the basis of the original sample of calcined magnesite.

Results are given in Table IX. They indicate that the amount of lime reacting in such oxychloride cement mixtures is about midway between the amounts found by the water and by the magnesium chloride method. That they are considerably higher than the results found by leaching with water is, of course, good evidence that lime in other forms than that of calcium oxide or hydroxide does react in such cements in the ordinary mixes used in the field.

The results so far obtained have not entirely conformed to those reported by Duschak, who believes that all of the lime which will influence oxychloride cement formation can be leached out of a freshly burned sample of magnesite by water. It is suspected that the discrepancies in the results of the two laboratories may be

traced to the fact that the magnesites investigated here are commercial calcined magnesites which have, of course, been exposed to the air for varying periods during their shipment from the California producers, instead of being freshly burned samples such as were examined at Berkeley. Comparison was accordingly made between different methods as applied to freshly burned magnesite and to magnesites which had been exposed to the air for varying periods.

A sample of natural magnesite rock was burned for two hours at 750 deg., a burning condition which with this particular rock gave a good quality plastic calcined magnesite. Determinations of active lime were then made by three methods on this freshly burned product as well as on samples of it which were exposed on watch glasses to laboratory air for various periods of time. The results are shown in Table X. They are particularly interesting in indicating that the three methods correspond much more closely on freshly burned magnesite than they do on a material which has been weathered for a moderate period. This is further evidence that calcium carbonate may in certain instances behave as active lime and is a good argument for the adoption

TABLE IX. REACTION OF LIME IN OXYCHLORIDE CEMENTS COMPARED TO ACTIVE LIME ANALYSES

Magnesite No.	Age of Cement, Hr.	Per Cent Lime Reacting in Cement	Active Lime H ₂ O	Active Lime MgCl ₂

CHLORIDE SOLUTION METHOD PREFERABLE

For use on routine samples of commercial calcined magnesites, then, it is felt that in spite of its obvious advantages in speed and in ease of manipulation, determination of alkalinity of extract is not as truly representative of the content of active lime as is the value arrived at by application of the magnesium chloride method. It is very probable that on freshly burned material, particularly on calcined magnesites burned at such a temperature as to completely remove the carbon dioxide from the lime, the water method will give results of approximately the same value as those found by the other procedure. This circumstance may make the water method of value to a producer, but cannot give it first place for use by a magnesite consumer, located a considerable distance from the calcining plant.

An additional argument for use of the magnesium chloride method for active lime is found in the fact that a definite relationship between certain physical properties of oxychloride cements and active lime content of the calcined magnesites employed, as determined by the magnesium chloride method, has been found to exist. In view of the lack of parallelism of results obtained by

the three methods, such a relationship obviously would not apply if free lime, determined by leaching with water or sodium chloride solution, were considered.

It is unnecessary to go into detail at this time on the methods used for physical testing of oxychloride cements and on the meanings of the various determinations as they have recently been published in this journal.³ It need only be pointed out that a determination of the water resistance of oxychloride cements as defined by the relation between strengths of the dry cement and strength after wetting is of great interest as pointing to the comparative permanence of different products. A test of this type is conveniently made by determining the modulus of rupture of flat bars of the oxychloride cement $\frac{1}{2}$ in. thick under three conditions—namely, dry, immediately after wetting for a definite period, and after wetting and redrying for a definite time. The standard procedure in making water-resistance tests in this laboratory involves preparation and aging of the bars for fourteen days, spraying some of the bars for three 24-hr. periods with intervening 24-hr. drying periods and determination of the strength immediately after final spraying and after forty-eight hours additional drying in comparison with the strength of unsprayed bars. Water resistance is expressed both as the percentage of strength retained after wetting and after wetting and drying and as the "classification factor" of the magnesite, this being a numerical expression involving wet, dry and recovered strengths, the wet strength appearing as the second power on account of its relatively great importance. The formula employed for its calculation is

$$\frac{(\text{Wet strength})^2 \times \text{recovered strength} \times 10}{(\text{Dry strength})^2}$$

The derivation of this expression may be clearer if it be considered in the form

$$\left(\frac{\text{Wet strength as per cent of dry strength}}{\text{of dry strength}} \right)^2 \times \left(\frac{\text{recovered strength as per cent of dry strength}}{\text{per cent of dry strength}} \right) \times \left(\frac{\text{dry strength}}{\text{in lb. per sq.in.}} \right) \times 100,000$$

³CHEM. & MET. ENG., vol. 25, No. 6, p. 233, Aug. 10, 1921.

This reduces to the same fraction as that given above. The constant term is introduced merely to give a number of reasonable size.

All such water-resistance tests are made on an oxychloride cement containing 12.5 per cent of calcined magnesite, 25 per cent of ground silica or silix, and 62.5 per cent of standard sand. These ingredients are mixed with a magnesium chloride solution of 22 deg. Bé. The reason for the adoption of such a test procedure cannot be discussed in detail here, but some results obtained by the application of this test may prove of interest.

In Table XI are given water-resistance tests made by this method on thirty-one different magnesites in comparison with analytical determinations of different constituents. Careful examination of the table will show that there is no relation whatever between the physical strengths reported and the per cent ignition loss, carbon dioxide, silica, iron and aluminum oxides, or total calcium oxide. It will be noted that the magnesites in the table are arranged in the order of their content of active lime. A study of the table will show that there is apparently no relation between the per cent of this ingredient and the physical tests reported. Experience has shown that other factors in the composition of a calcined magnesite not expressible by chemical analysis have such a vital influence on the strength and permanence of the oxychloride cements resulting that they are apt to obscure any relation existing between lime content and physical strengths when a single sample of magnesite is considered. Only when a sufficient number of determinations are averaged to cancel out these other factors would it be expected that the real relationship would appear.

Such average results are given in Table XII. In this the magnesites are divided into four classes depending on their content of active lime. If the mean values of active lime for each class are compared with the average physical strengths for each class, a definite relationship will at once become apparent. Per cent wet strength decreases rapidly as the content of active lime increases. This relation is brought out perhaps more clearly by Fig. 1, which shows graphically the relation between

FIG. 1. RELATION BETWEEN WET AND RECOVERED STRENGTH AND PER CENT OF ACTIVE LIME

which will be brought about by active lime. The amount of water in the mix will remain essentially unchanged, but magnesium chloride will be removed by chemical action and the resulting solution will have a lower content of this salt than that originally used for the mixture. Such a reduction radically reduces the strength and water resistance of oxychloride cements, as is shown from Table XIV, which gives the average results of reduction in chloride strength from 22 to 20 deg., Bé. on five different magnesites.

TABLE XIV. EFFECT OF CHLORIDE STRENGTH ON PHYSICAL PROPERTIES OF OXYCHLORIDE CEMENT			
Gravity of Chloride Solution, Deg. Bé.	Average of Five Magnesites		
	Modulus of Rupture		
	Dry	Wet	Recovered
22	1,453	616	890
20	1,293	417	827

In the 1:2:5 mix employed for these tests, in which approximately 1.3 c.c. of magnesium chloride solution will be required for each gram of magnesium oxide used, the presence of 1 per cent of free lime in the calcined magnesite will result in a reduction in gravity of the magnesium chloride solution of approximately 1 deg. Bé., together with the introduction of an amount of calcium chloride equal to about 3 per cent of the $MgCl_2 \cdot 6H_2O$ present. When the summation of these two effects is considered, it is not at all surprising that the influence of active lime is as striking as it is.

Although a definite relation has been found to exist between active lime content and physical properties of an oxychloride cement produced from a given magnesite, it should be thoroughly understood that such an effect is observable only when results from a large number of magnesites are averaged. Important as the effect is, it can very easily be overbalanced by other factors. It is not safe, accordingly, to say that a magnesite having any definite percentage of active lime is dangerous or that one containing active lime lower than certain amounts will be a good product. The results should not be taken as any argument for the adoption of chemical tests for calcined magnesite, but merely as an additional indication of the necessity of the investigation of the physical properties of the oxychloride cements produced from a given sample of plastic calcined magnesite before any definite conclusion as to the quality of this material can be reached.

SUMMARY

Methods for determination of "free" and of "active" lime in plastic calcined magnesites have been indicated, and the distinction between total lime and active lime in such a material brought out.

A relation between active lime content of calcined magnesites and physical properties of the oxychloride cements produced from them has been brought out.

The relationship between active lime content and physical properties of oxychloride is apparent only when average results from many samples are considered. Other factors may completely obscure the relation in a test on a single sample.

Active lime content is accordingly not a definite indication of poor quality in a magnesite, although a magnesite containing active lime in large amount should be regarded with suspicion.

Physical tests of oxychloride cements must still be regarded as the only safe criterion of the quality of magnesites used in the oxychloride industries.

National Kellastone Co.
Chicago, Ill.

TABLE XII. RELATION BETWEEN ACTIVE LIME AND PHYSICAL PROPERTIES—AVERAGE RESULTS

Per Cent Active Lime	Mean Value	Wet Strength as per Cent	Recovered Strength as per Cent	Dry Strength, Lb.	Per Cent Total CaO	Classification Factor	Per Cent Free Lime
0-1.5	1.27	49	84	1,221	3.85	2,460	0.45
1.5-2.0	1.62	38	74	1,390	2.95	1,490	0.49
2.0-2.5	2.28	32	60	1,182	2.23	730	0.87
2.5-4.0	2.92	16	37	1,234	4.20	116	0.62

In both Tables XI and XII the per cent of free lime, as indicated by the water solubility method previously described, is given for comparison. It is evident that this determination bears no direct relation to physical properties of the oxychloride cements.

Some explanation for the phenomena noted must be sought. The presence of active lime in a calcined magnesite will result in two different actions. In the first place calcium chloride will be introduced into the magnesium chloride solution. The effect of such an introduction on physical strengths is brought out from Table XIII, which shows that when any large amount

TABLE XIII. EFFECT OF CALCIUM CHLORIDE ON PHYSICAL PROPERTIES OF OXYCHLORIDE

Per Cent $CaCl_2$ Added to $MgCl_2$	Modulus of Rupture		
	Dry	Wet	Recovered
0	1,158	604	828
5	936	432	768
10	570	114	240

of calcium chloride is added a marked reduction in the strength and water resistance of the oxychloride cement appears.

An even more important feature affecting the physical strength is the reduction in gravity of chloride solution

Internal Service-Strains in Steel*

Discusses the Effect Which Forces and Movements Taking Place Within the Metal Itself, Between Crystals and Even Between Atoms, Induced by Conditions Other Than External Loading, May Have Upon the Successful Employment of Steel in Industry

BY JAMES E. HOWARD†

DISCUSSIONS upon the properties of materials have seldom taken so important a direction as that which is called for under the present general discussion. In general, the ultimate object of employing the materials of construction is to utilize their ability to resist stresses. Their value depends upon their ability to endure successfully stresses of different degrees continued over different intervals of time, having reference to the external loads which are imposed upon them.

Practically all of the materials of construction are affected by internal strains. Opposing internal strains may be present in individual members when apparently they are in a state of repose; that is, when no external forces are acting upon them. These internal strains are no less real than those which are the direct results of external loads. The resultant strains in any given member, under working conditions, is the algebraic sum of the internal strains and those which are caused by external loads.

STRAINS MAY BE RESIDUAL OR ACQUIRED

Under many conditions of service the state of internal strain of the material demands consideration. This is peculiarly the case with steel rails which are exposed to destructive forces and which acquire in service internal strains of high degree. Bridge members acquire internal strains, cooling strains during fabrication of component parts and strains when they are assembled, to which are finally added those due to dead and live loads.

The original properties of materials are generally made the subject of careful determination, while scant consideration has been given those phases through which materials pass under exposure to service conditions, involving the introduction of internal strains which at times culminate in rupture. These original properties may be imparted to steel by various means, by chemical composition, by heat and by mechanical treatment. The ability of the steel to resist different stresses in service is not definitely shown by the values of the original properties. It is commonly assumed that a favorable relation exists between the original properties and service stresses, when certain initial properties are imparted to the steel, furnishing a reason for imposing exacting requirements upon their original state, although the relations have not been clearly established.

It is a very welcome diversion therefore to have attention invited to the subject of internal strains and the effects of prolonged stresses, matters which are so intimately connected with the safe and proper use

of materials. It is somewhat difficult nevertheless in taking up a subject so comprehensive as the present one to choose the features to be commented upon. Attention, however, will be directed to certain features which are among those less frequently taken into consideration in discussions upon the physical properties of steel. Reference will only be made to examples which have come within the experience of the writer.

STRENGTH DEPENDS ON CONDITIONS OF LOADING

In dealing with steel a query is at once suggested; namely, what constitutes the maximum range in strains which steel will endure, under either temporary or permanent loads and without loss of integrity. Temporary strains of tension in steel music wire have been shown amounting to 0.015 per unit of length. Under stress of compression, hardened steel endures a strain of 0.020 per unit of length. These strains represent stresses of 450,000 and 600,000 lb. per sq.in. respectively. They stand as extreme examples of elastic extension and compression which have come to notice, and are far beyond any elastic strains made use of in the arts. Music wire, in the upper octaves of a pianoforte, probably affords an example of maximum working stresses under which steel is placed for long continued periods, strains of about 0.006 per unit of length, more or less.

Examples of reversed strains, in the same member, have not been observed approaching those which steel has displayed while under stresses in one direction only. Steel subjected to alternate stresses of 50,000 lb. per sq.in. tension and compression each has shown apparently complete restoration in length after release of stress, thus showing an aggregate elastic movement of 0.003½ per unit of length. Its ability to display this aggregate movement was impaired when over-straining loads in either direction were applied; loads which caused the introduction of permanent sets of either tension or compression.

Herein is observed the effect of a structural change resulting from stresses which permanently disturb the relative positions of the component parts of the steel. It appears to be a characteristic of the effect of alternate stresses that a reversal of direction of strain is attended with less total or aggregate elastic resilience than steel is capable of displaying when strained in one direction only. It is doubtful whether steel will be found which will endure long continued alternate stresses, in which the strains exceed a small percentage of the aggregate strains of tension and compression in separate members. In the experience of the writer the limiting stress, under repeated alternate stresses, which steels are capable of enduring 100,000,000 repetitions or more is in the vicinity of 45,000 lb. per sq.in.

*A contribution to a general discussion on "The Failure of Metals Under Internal and Prolonged Stress," held by the Faraday Society, April, 1921.

†Engineer Physicist, Interstate Commerce Commission, Washington, D. C.

In commenting upon this feature years ago, Shreve inferred from the results of Wöhler and Spangenberg that 30,000 lb. per sq.in. was the limiting stress for irons.

STRENGTH IN CUBIC COMPRESSION

Judging from experience with other materials and noting also that no change occurs in the physical properties of mild steels after exposure to cubic compression several times the elastic limit in tension, it is inferred that steels will endure cubic compression without limit. Destruction of integrity of a material results from separation of the adjacent particles, but that integrity does not admit of being impaired by forces of compression when received simultaneously in three directions, however great those forces may be. It follows that the maximum intensity of a force of compression may be very great without injury provided there is a progressive graduation from the center of effort to the periphery of the stressed area. For this reason intense impinging pressures such as those which occur between the head of a rail and the tread of a wheel, although injurious, are less damaging to the metal either of the rail or wheel than such pressures would be under conditions of uniformly distributed stresses.

In a sense, the most stable condition in which steel exists is the annealed state. It was early observed that the value of the modulus of elasticity of steel was modified when the metal was materially overstrained and had received a substantial permanent set. This value is temporarily lowered. A stress-strain curve with the steel in this condition shows an area of lost work, between ascending and descending stresses. A struggle apparently goes on within the steel to recover from this overstrained state, and after the lapse of a few days or weeks the normal value of the modulus is regained.

INTERNAL STRAINS IN FORGED OR ROLLED STEEL

The denseness of steel is modified by treatment. Heating and quenching, annealing and cold working, all result in changes in volume. It has even been found that changes in the dimensions of forgings take place more in one direction than another. By means of a strain gage, forgings have been found to contract when annealed more in length than in lateral directions. In this behavior of forgings there appears to be evidence of an interstructural or intermolecular state of strain which affects the general mass of the metal. This is not the usual manner of strain in which one portion of the volume in a state of internal compression is balanced by another part of the volume in a state of tension, but a diffused state of strain in which the microconstituents may play the principal parts.

Not unlikely a relation may exist between the viscous resistance of steel at forging temperatures and this interstructural state of strain. The behavior of steel forgings in this respect suggests an interesting line of inquiry.

Internal strains make their appearance in steel cooled from the ingot or cooled after the operations of forging or rolling. The parts first to cool are usually left in a final state of compression, unless modified by complexity of form in the steel member. Earlier strains in the steel, experienced during the period of cooling, are reversed in the cold metal.

Under normal conditions of air cooling, internal

strains are modified by the cross-section dimensions of the steel member. Since the acquisition of internal strains is influenced by the rate of cooling, large forgings of compact form are expected to be less affected than forgings or rolled shapes having thin webs and flanges. In steel rails, with thin flanges, internal strains of compression not infrequently reach a magnitude equivalent to a stress of 15,000 lb. per sq.in. In the heads of the heavier rails cooling strains equivalent to 5,000 lb. per sq.in. compression represent ordinary values.

Steel structural members, channels, angles and plates also acquire cooling strains after they emerge from the rolls. Built-up compression members, of which they may form component parts, will initially contain cooling strains of considerable magnitude. Recent examinations of structural shapes have shown the presence of internal strains of compression equivalent to 12,000 lb. per sq.in. This value is three-fourths of the usual allowable stress for compression member in current engineering practice. Since no account is usually taken of the presence of internal strains in structural members exposed to compressive stresses, the omission is worthy of note.

COOLING AND QUENCHING STRAINS

The usual range of internal strains in air-cooled steel members may be greatly extended by accelerated rate of cooling, by exposure to a current of air, by an air blast, or by cooling with water from a medium high temperature, but not so high as to result in thermal hardening. Rapid cooling of steel rails from the finishing temperatures of the rail mill by means of an air blast is capable of introducing internal strains of compression exceeding 40,000 lb. per sq.in. Forgings reheated to about 900 deg. F. and cooled with water acquire internal strains of compression comparable with those resulting from an air blast on rails at finishing temperatures.

Local heating followed by normal air cooling also results in the introduction of internal strains; that is to say, unequal heating of steel, as well as unequal cooling, is a cause for internal strains. By means of an oxy-acetylene torch internal strains may be introduced, and changes in dimensions effected at will, either in plus or minus directions, according to the locality on which the torch is applied. The side of the member locally heated finally contracts in length while the opposite side expands. The heated side dilates, is overstrained by the cooler and stronger side and is eventually shortened. Admonitions upon the manner of heating and quenching machine small tools are based upon causes such as here described.

Heating by frictional resistance and quenching by the conductivity of the cold surrounding metal introduce internal strains and lead to the rupture of metals. Brake shoes in railway service furnish familiar examples of such action. The treads of wheels are occasionally affected in like manner. Examples of "wheel-burnt" rails, so called, are numbered by thousands, that is rails which have been intensely heated along elements on the running surface of the head by the slipping of wheels. All phases of heating, quenching and annealing are confined within shallow depths of metal on the heads of those rails, and this occasionally results in rupture. The severe structural effects which may result from wheel burning will be realized upon giving consideration to the difference in the rate of transmission of heat through the cross-section of the rail and the rate of transmission of strains.

It is necessary to exercise care in machine tool operations to avoid the introduction of internal strains. A light feed and depth of cut, employing a tool with a sharp cutting edge, is necessary in the machining of steel in a lathe or planer to avoid the introduction of internal strains. Internal strains of compression are commonly introduced in machine operations. It has been found, however, that excessive cuts and feeds may result in the introduction of strains of tension. Punching and shearing of steel for use in important places has long been objected to. The introduction of high-speed, blue-chip, tool steels has brought about machine tool practice encroaching upon the objectionable features of punching and shearing.

EFFECT OF COLD ROLLING ON STEEL RAILS

The introduction of internal strains of most common occurrence is found in the case of steel rails in railway service. All rails are cold rolled and acquire a state of internal strain resulting from the wheel pressures. Cooling strains resulting from manufacture are present in the rails when placed in the track. These strains in part remain unaffected by subsequent conditions of service. Those in the flanges of the base commonly remain undisturbed. It is quite a different affair, however, in the head of the rail. Here the original cooling strains are immediately augmented by the wheel pressures. Internal strains in the rail head next the running surface not infrequently attain a magnitude equivalent to 20,000 lb. per sq.in. stress. The internal strains next to the running surface are those of compression.

Necessarily there must be strains of tension in some part of the cross-section of the rail to furnish the required reaction. They are found along the central zone of the head, where the measured values have reached 8,000 lb. per sq.in. tension.

This condition acquired by the rails in the track is the explanation, in the opinion of the writer, which accounts for the development of transverse fissures. The most strained fibers in tension in the head are interior fibers. Transverse fissures commonly have their origins in eccentric position, the majority being located on the gage side of the head. No other common cause has been found to account for the formation of these fissures of interior origin.

SHATTERED ZONES AND BRITTLENESS UNDER CUBIC TENSION

Shattered zones have been found in some rails along the center line of the head and at the junction of the web and the base. No failure has resulted from the shattered zone in the base. It has not been ascertained whether the presence of shattered metal in the head promotes the development of transverse fissures by furnishing a nucleus from which they may extend or on the other hand whether the internal strains caused by the wheel pressures are diffused and expended in the looseness of the central zone when shattered metal is present. Shattered rails are found which have not displayed transverse fissures and transverse fissured rails are met in which there is no evidence of a shattered zone.

These shattered zones appear to be the result of shrinkage strains, acquired when the rail is cooling, after the last pass in the rail mill. The shattered metal does not extend to the hot sawed ends of the rails, but terminates about the same distance from the rail ends as the distance in from the peripheral metal of the

head to the shattered zone. This circumstance fixes the period during which these zones are formed.

The idea does not appear untenable that brittleness, in the sense of inability to display permanent extension, may be displayed by steel at any temperature, under conditions of cubic tension. The only opportunity for steel to reach such a state, in which there are simultaneous strains of tension in three directions, seems to be during the operation of cooling at the period when the peripheral metal has reached a state of compression and exerts tension on the interior. At some stage during the operation of cooling there is a reversal of strain from tension to compression in the peripheral metal. The higher the temperature at which this reversal takes place, the lower the prevailing tensile strength of the steel. At the finishing temperature of rails, while there is considerable viscous resistance to the steel, it then has but little tensile strength. Even with a lowered modulus of elasticity at finishing temperatures only a minute strain would seem necessary to separate adjacent particles and prove adequate to cause these shattering cracks. Since all forged and rolled shapes are subject to cooling strains of this kind, it is obviously desirable to clear up matters connected with the phenomenon. As the case now stands, shattered zones have been found in some rails and not in others. Those which have displayed this phenomenon, by chance or otherwise, have been of the harder grades of steel.

EFFECTS OF SURFACE DEFECTS

A slight surface defect or interruption in continuity is known to have a serious effect on steels exposed to repeated alternate stresses, leading to premature rupture. This is quite evident from the failure of steels in which the structural defect was located remote from the plane of maximum fiber stress. The rupture of steel occurs when two adjacent particles are separated beyond their radius of action or molecular bond, whatever descriptive term may be used in this connection. Progressive fractures develop under such conditions. Since the presence of a surface defect produces a result similar to an increased fiber stress on the metal as a whole, it is inferred that an actual increase in fiber stress is experienced in the vicinity of the defect. Carrying the inference one step farther, it appears reasonable to believe that internal strains may augment those of external origin, the algebraic sum of the two representing the actual fiber stresses which affect the steel. Carrying the inference still farther, although now approaching a debatable state, it may be argued that actual separation of adjacent particles occurs when and only when the local strain between them reaches a maximum and that this maximum has a relation to the original tensile strength of the steel. In support of this last inference is the behavior of steel under repeated alternate stresses conducted at different temperatures. At a blue heat, in the range of 400 deg. and 600 deg. F., at which period the tensile strength is above that at ordinary temperatures, steels under repeated stresses endure several times the number of repeated loads which they sustain at atmospheric temperatures. That is at the time of increased tensile strength there is an accompanying increase in its endurance of repeated stresses.

A field but partially explored presents itself in tracing the phases through which steels pass in their approach to the final stage of rupture, involving among

others the query at what stage and by means of what treatment can the progress of rupture be arrested and the steel restored to its original state. Unlimited endurance, in a practical sense, is now experienced by limiting the fiber stresses within a certain range. High initial physical properties are imparted to steels by special treatment, heat and mechanical. The question of ultimate endurance is not fully met by subjecting steels of exceptionally high original properties to a comparatively small number of alternate stresses. Results already gained are gratifying but they still leave undetermined basic questions pertaining to long continued stresses.

Stress-strain curves under loads once applied and advanced until rupture takes place, as performed in ordinary tests by tension, are practically straight lines until the elastic limit is reached. Early sets, if such appear, may conjecturally be attributed to the influence of internal strains pre-existing in the steel, in localities where the elastic limit is reached prior to that of the general mass of the metal. There is lack of harmony between the opinion often expressed that a permanent set occurs under every stress however small it may be, and the example of music wire sustaining stresses far above 100,000 lb. per sq.in. over periods of years and with the ability to sustain a temporary stress of 460,000 lb. per sq.in. tension.

Evidence does not seem to have been presented in support of the statement that any stress however small will cause a permanent set in steel, and that perfect elasticity or complete resilience after the application of a force of tension does not constitute a fundamental property in steels. The limited consideration which has been given to the matter of internal strains is believed to account for certain popular impressions.

In conclusion, it may again be remarked that attention has commonly centered upon the original properties and characteristics of steels, and the means by which these original properties are modified, overlooking the wide range of conditions which affect the endurance of the metal, the phases through which steels pass under conditions of service, and which lead in the direction of ultimate rupture.

German Sales of Potash

According to a recent dispatch from Berlin 419,000 metric tons of potash (K_2O) was sold in Germany between Jan. 1 and July 31, 1921. It is reported that the inland prices received did not cover the cost of production and that the profits on foreign sales of the same material were less than in the like period of 1920.

Phosphates in Morocco

The first shipment of 300 tons of phosphates has just been made from Onedzem according to a dispatch from Casablanca, Morocco, dated Aug. 2. This is regarded as an industrial event of prime importance, in view of the enormous beds of this material now awaiting development in the Onedzem district.

Rumania Abolishes Export Duties on Some Chemical Products

A decree issued by the Rumanian government on Aug. 1 states that export taxes on the following chemical products have been abolished: alcohol, glucose, calcined and crystallized soda, sulphuric and acetic ethers, amylacetate and crude sulphuric acid.

Comparative List of Imports and Exports of Chemicals for Fiscal Year Ended June 30, 1921

Imports decreased 43 per cent, exports decreased 25 per cent during the fiscal year 1921 compared with 1920, according to official figures of the Department of Commerce just made public. An analysis of imports shows that crude materials fell from \$2,141,000,000 in 1920 to \$1,051,000,000 for the year just closed, indicating that mill consumption fell off materially during 1921, hence the lessened demand for the raw materials of foreign countries. Imports of crude foodstuffs and food animals fell from \$622,000,000 to \$452,000,000; of manufactured foodstuffs, from \$891,000,000 to \$842,000,000, or a decline of \$219,000,000 in our purchases of foreign products.

The emergency tariff act became effective May 27. During May we imported about \$62,000,000 worth of foodstuffs, crude and prepared, while in June the total of these imports was \$40,000,000.

Manufactures for further use in manufacturing fell from \$801,000,000 to \$543,000,000, again reflecting the depression in industry. But imports of completed manufactures scored a decrease of but \$1,000,000, or from \$745,000,000 to \$744,000,000 in value. The pre-war average was under \$450,000,000.

On the export side of the sheet crude materials decreased from \$1,969,000,000 to \$1,288,000,000, the two years compared. A falling off in sales to other countries which have been fairly well stocked with American crudes was somewhat balanced by increased purchases on the part of Germany. Crude foodstuffs increased from \$626,000,000 to \$979,000,000, being the only group to show an increase over 1920. Manufactured foodstuffs fell off from \$1,514,000,000 to \$779,000,000. Partly manufactured goods decreased from \$991,000,000 to \$687,000,000, while completed manufactures showed a decrease from \$2,835,000,000 to \$2,643,000,000.

To sum up, our imports decreased from \$5,238,000,000 in 1920 to \$3,654,000,000 in 1921, while our exports decreased from \$8,109,000,000 to \$5,516,000,000. This includes the miscellaneous group and foreign merchandise exported.

Handbook on Shellac Industry in India

The Government of India has issued a "Report on Lac and Shellac" as part of "Indian Forest Records," which Trade Commissioner C. C. Batchelder believes to be very useful and of interest to users of shellac. It is a comprehensive book, the result of investigations made into the sources of supply, methods of production, manufacture, transportation and distribution, fluctuations of prices and volume of exports. It not only shows in a colored map the places where the lac is produced, but presents graphically in charts the variations in London and Calcutta prices from 1901 to 1919, with the London stocks and the effect of large stocks upon Calcutta prices.

Explanations are given of the variations in quality due to methods of preparation and cultivation, together with much other technical information, such as the way to restore the solubility of relatively insoluble shellac.

Of immediate practical use are the lists of the principal manufacturers, dealers, and exporters in the different lac centers. There is also a list of other literature on the subject.

Decision in Bakelite Patent Suit

THE U. S. District Court, Eastern District of New York, on Aug. 2, 1921, rendered its decision in the patent suit of the General Bakelite Co. of New York vs. the General Insulate Co. of Brooklyn. Three Bakelite patents relating to various uses and applications of synthetic resins were involved and all were declared valid and infringed.

The original bill of complaint was filed by the Bakelite Company on Sept. 18, 1917, and the trial, which began on March 31, 1919, was not concluded until June 22, 1919. The counsel for the General Bakelite Co. were Charles Neave and Maxwell Barus, of Fish, Richardson & Neave, and C. P. Townsend, of Byrnes, Townsend & Brickenstein. John H. Lee, of Dyrenforth, Lee, Critton & Wiles, and J. Edgar Bull, of Gifford & Bull, were counsel for the defendant. The trial was conducted before Judge Thomas I. Chatfield.

It will be recalled that in a previous patent suit¹ against George J. Nickolas & Co. of Chicago, where three other Bakelite patents were involved—namely, Nos. 954,666, 1,018,385 and 1,037,719, covering specifically the manufacture of Bakelite varnishes and solutions—the General Bakelite Co. obtained a decree adjudicating the validity and infringement of these patents.

The General Insulate Co. of Brooklyn is engaged in a molding business and produces insulating material resembling hard rubber. It uses as its raw material the synthetic resin, purchased from the Redmanol Chemical Products Co. of Chicago, either in the form of a fine powder or as hard, brittle sheets. The case necessarily involved consideration of the character of the Redmanol product, and that company, although it was not a party to the suit, stood behind the defendant in all matters relating to patentability. To quote from the opinion of the court, "the Redmanol company has as freely and fully presented its evidence as if the action had been against the Redmanol company, for infringement of the plaintiff's patents, in the manufacture of the synthetic gum itself."

CLAIMS OF THE PATENTS IN ISSUE

The suit was brought on the following United States patents: The so-called heat and pressure patent, No. 942,699, which grew out of an application filed July 13, 1907; the indurated product patent, No. 942,852, which was a division of the application of the previous patent; and the so-called mixture or molding patent, No. 939,966, which was issued upon an application filed Jan. 28, 1909.

The following claims were in suit in the first patent:

"1. The method of producing a hard, compact, insoluble and infusible condensation product of phenols and formaldehyde, which consists in reacting upon a phenolic body with formaldehyde, and then converting the product into a hard, insoluble and infusible body by the combined action of heat and pressure."

"2. The method of making articles containing an insoluble and infusible condensation product of phenols and formaldehyde, which consists in reacting upon a phenolic body with formaldehyde, producing thereby a reaction product capable of transformation by heat into an insoluble and infusible body, forming the article from said reaction product, and rendering the article hard, insoluble and infusible by application of heat and pressure."

"4. The method of making articles containing an insoluble and infusible condensation product of phenols and formaldehyde, which consists in reacting upon a

phenolic body with formaldehyde, producing thereby a reaction product capable of transformation by heat into an insoluble and infusible body, forming the article from said reaction product compounded with a filling material, and rendering the article hard, insoluble and infusible by application of heat and pressure."

The claims in issue in the next patent are 5 and 6:

"5. As a new composition of matter, wood cell tissue impregnated with an infusible and insoluble condensation product of phenol and formaldehyde."

"6. As a new composition of matter, a fibrous or cellular material impregnated with an infusible and insoluble condensation product of phenol and formaldehyde."

The claims of patent No. 939,966 in suit are:

"1. The method of molding articles which consists in comminuting a partial reaction product of phenol and formaldehyde, molding the mass under pressure, and transforming the same into an insoluble and infusible condensation product."

"2. The method of molding articles which consists in comminuting a partial reaction product of phenol and formaldehyde, molding the mass under pressure, and transforming the same in the mold into an insoluble and infusible condensation product."

"3. The method of molding articles, which consists in preparing a comminuted mixture of a partial reaction product of phenol and formaldehyde and a filling material, molding said mixture and transforming the partial reaction product into an insoluble and infusible final condensation product."

The prior patents relating to the subject of molding and hot pressing are dismissed with the statement:

They taught nothing as to the creation of synthetic condensation products, and left the prior art with mere knowledge of melting, dissolving, solidifying, pressing, turning, boring, polishing and cutting materials, which proved the demand for substances which were never thought of until phenolic condensation products were discovered.

THE MANASSE, LUFT AND STORY PATENTS

Detailed consideration, however, was given to the few patents for the prior art of making synthetic compounds of phenols with formaldehyde. Among these the ones of particular interest are the patents of Manasse, Luft and Story. The following paragraphs referring to the history and extent of these patents are abstracted from Judge Chatfield's opinion:

The earliest patent that should be considered is that issued to Otto Manasse, in the United States, No. 526,786, Oct. 2, 1894. Manasse was seeking to describe a method or process of producing phenol-alcohols by using alkaline or neutral condensing agents, in aid of the reaction of formaldehyde on phenol or phenol-like substances. After mixing the phenol dissolved in the alkaline or neutral condensing agent with formaldehyde, and acidulating the resultant mixture, he separates the oxybenzylalcohol from the watery solution by extraction by ether. He then evaporates the solution so as to obtain a semi-fluid mixture which is treated with steam, thus driving off the residues of formaldehyde and phenol which have not entered the reaction. On cooling and filtering a resinous body is left, which apparently is the synthetic product in which both the plaintiff and the defendant in this case are interested. But Manasse rejects this resin and treats further the solution in order to obtain crystals, which in turn, when dissolved in benzene show a separation of oxybenzylalcohol from the parahydroxy-benzylalcohol which remains in the form of an amorphous powder in the solution.

Luft states (U. S. Patent 735,278, Aug. 4, 1903) that he is seeking to obtain a plastic compound, which in the German patent he calls a "resinous mass," by making use of the "known fact that upon boiling phenols with aldehydes, and especially with formaldehyde, in the presence of acid, a mass results which when fresh is viscous and very plastic," and is capable of use in the arts.

Luft apparently began to work with the resinous mass which Manasse filtered out and discarded.

Luft's process is expensive, and he never, so far as his own knowledge or the disclosure of his patent is concerned, got beyond the fusible and soluble state. It is

¹CHEM. & MET. ENG., vol. 13, No. 7, p. 711, July, 1915.

evident, as was shown in court, that present knowledge of the art in the hands of an expert makes it possible so to manipulate the Luft process as to produce an insoluble and infusible final product, but Luft never did this nor taught it by his patent disclosure alone.

The Story patents, British, No. 8,875, of 1905, French, No. 353,995; of Sept. 25, 1905, and the French Addition, No. 9,861, applied for Sept. 29, 1908, describe the production of a condensation product by the action of aldehydes on phenols.

Story uses commercial carbolic acid containing 95 per cent of phenols with formalin containing about 40 per cent of formaldehyde. He pours his viscous product into molds which he dries at a temperature below 100 deg. C. He takes 50 parts of commercial carbolic acid and 30 parts of formalin and produces a substance which, having once become hard and dry, he states is insoluble in any known solvent and is not attacked by acids or alkalis. He states that in the viscous state it may be dissolved in alcohol, acetone, benzol or other suitable solvent, and furnishes a good varnish for many purposes, from which the solvent may be removed by heat.

The Story patent is particularly interesting because the Redmanol company manufactures and is putting upon the market in large quantities a product which evidently is produced according to the Story description. This result is obtained by long drying and heating, in some instances this period of heating at temperatures around 50 deg. C. lasting for over a year. Story suggests the adding of coloring matter or inert substances while in gelatinous state, and suggests in the addition patent drying at much higher temperatures in order to produce hardness and insolubility.

Experiments during the course of the trial have satisfactorily shown that Story, as well as Luft and De Laire, can be ultimately operated so as to produce the infusible and insoluble substance which is known as "Bakelite C." This is the same substance which is shown and described in the Aylesworth U. S. patent, and which is also referred to in U. S. patent to Stephan, No. 812,608, Feb. 13, 1906, on application filed Dec. 6, 1904. But Stephan was seeking to make an antiseptic powder. His insoluble product was an accidental and not desired substance, obtained if his compound was heated too long. He produced an acid product, and certainly was not teaching the production of the insoluble substance, nor did he anticipate any of the other patents under consideration.

BAEKELAND'S PATENTS

The earliest application of any one of the Baekeland patents was Feb. 18, 1907, and the public description of Baekeland's researches was made in 1909, when various articles were read before the New York Section of the American Chemical Society, and printed in the *Journal of Industrial and Engineering Chemistry* during that year. These dates will become of importance when we consider that the Baekeland patent involving the use of hexamethylenetetramin, which patent was in interference in the Patent Office with applications by Redman, Goldsmith and Steinmetz, and out of which interference a patent was issued to Goldsmith for the so-called dry hexamethylenetetramin method, and to Baekeland for the wet hexamethylenetetramin method. The date is also important in connection with the defendant's claim that Baekeland did not know of the prior art patents when he applied for the heat and pressure patent in 1907. But he discussed these patents in his amendments of March 17, 1908.

Evidently Baekeland was aware of the chemical formation of hexa as early as the proceedings in the Patent Office resulting in Patent No. 942,809, which was issued Dec. 7, 1909. He specifies the use of ammonia as early as October, 1907 (application No. 397,560). There seems to be no reason why his patent No. 1,038,475 should be held invalid because it makes use of certain knowledge described in a co-pending application, even though that co-pending application was of an earlier date.

Even if Redman was entitled to a valid patent for the description of the preparations used by him in the so-called dry hexa method, the defendant using the Redman product would still be liable to a charge of infringement of the patents in suit, whether the hexa be added in a two-step or a one-step process, or in a wet or dry reaction. But the two-step process has in some respects a commercial advantage.

It is also urged that the use of hexa does not in any

event infringe the Baekeland patents calling for use of formaldehyde and ammonia. This is a mere verbal argument, as hexa is well within the limit of equivalents but may still be the basis for an improvement of the method patent.

The defendant seeks to escape the charge of infringement by urging the defense presented by the Redmanol company, that hexa was not covered or disclosed by the specifications and claims of any of the Baekeland patents, until Patent No. 1,038,475, and that the use of hexa by Redman constituted a new invention, giving him the right not only to manufacture synthetic reactive gums, with this substance and with carbolic acid, but also to make the various products by the use of dyes and fillers and the employment of molding processes, which Baekeland has attempted to obtain by the patents in suit, and the others described in this case.

FORMALDEHYDE AND AMMONIA EQUIVALENT TO HEXA

As has been stated in his earlier patents, Baekeland discloses the use of substances engendering formaldehyde. It is apparent that hexa is immediately formed upon the introduction of ammonia and formaldehyde. The independent discovery by Redman of the possibility of using hexa, in order to avoid the necessity of drying out the water or moisture remaining in the original reaction product, was antedated by Baekeland's writings and patent specifications, which specifically claim ammonia and the substances engendering ammonia as a part of the Baekeland series of inventions. Redman's invention is therefore dependent upon his methods of manufacture at atmospheric pressure and with a dry compound of formaldehyde and ammonia, rather than from the use of hexa as such.

The use of hexa, therefore, does not get the synthetic gum outside of the Baekeland disclosures and claims. If the defendant makes use of the processes patented by Baekeland, when applied to the substances described by Baekeland, in the production of the commercial material covered by the Baekeland inventions, then it cannot escape the charge of infringement by showing that this material was produced by the Redmanol company with hexa, instead of with formaldehyde and ammonia separately. In other words, hexa is but an equivalent for formaldehyde and ammonia, and the defendant company is using this equivalent in carrying out the process of the Baekeland patent. In this sense the defendant is in a position analogous to a contributory infringer if the Redmanol company were a primary infringer.

CONTENTIONS OF THE DEFENDANT

The defendant contends that the specifications and claims of the heat and pressure patent (No. 942,699) show only, and that the evidence in the case proves that Baekeland had in mind only, the use of counter pressure to prevent violent expulsion of ammonia. It is claimed that he later attempted to include molding pressure, when he realized the need of securing the chemical reaction during the molding and heating process. But while the original claims were not as broad as those finally allowed and were evidently drawn without any attempt to include in words the molding pressure, the language of the specifications shows clearly both understanding of the need and use of molding pressure, and indicates Baekeland's intent to include it in his claims. His subsequent amendments were therefore allowable and there is no reason for limiting the valid range of the patent as issued.

In a similar way, the defendant argues that the only novel feature claimed in the indurated material patent (942,852) as originally presented, was to secure the removal of moisture during an old or well-known reaction for the purpose of impregnating or hardening wood. The separation of water was an essential step, but was not the only one disclosed, and the specifications fully support the claims as finally allowed. One of the materials to be indurated was cellular wood flour, and the impregnation and induration was had in order to make this into blocks or solids. The history of the patent in the Patent Office shows that Baekeland appreciated, at least, the possibility of claiming more than was expressed by the apparent understanding of the examiner and the present contention of the defendant.

The claims are valid and cover molding, with wood flour, and coloring material.

Patentability having been shown, the claims upheld in form and the defendant proved to have infringed, the plaintiff may have a decree.

The Chemistry, Manufacture and Uses of Nitrocellulose

History of Nitrocellulose — Relation to the Chemistry of Cellulose — Comparison of Early and Modern Methods of Manufacture—Military Demands for Smokeless Powder and Peace-Time Uses in Pyroxylin Plastics, Artificial Silk and Leather, in Medicine and Photography

By HUGO SCHLATTER

Formerly Chief of Chemical Products Division, Hercules Powder Co.

THE history of modern high explosives may be said to date from the middle of the last century, although picric acid and some of the fulminates were discovered much earlier. The early history and the discoverers of these products are therefore well known from contemporary literature, and in this respect they differ a great deal from the oldest explosive, black powder, whose history is shrouded in mystery. The year 1846 saw the discovery of both nitroglycerine and guncotton or nitrocellulose, both of which have played and are still playing such an important rôle in human history.

It is true that Braconnot and Pelouze had nitrated starch and paper some years earlier with nitric acid alone, but Schönbein, of Basel, first prepared nitrocellulose from absorbent cotton by means of a mixture of nitric and sulphuric acids, and realized its true significance and value.

A few weeks after this discovery the German Böttger obtained the same result and the two inventors combined to exploit the product. Schönbein had great hopes for his nitrocellulose. In a letter to Faraday he said that he expected that it would soon displace black powder as a propellant for firearms. It was many years, however, before this hope was realized, although a number of plants were put up in short order.

The first guncotton plant was erected in the same year at Faversham, in England, but in July of the next year the whole plant was destroyed by an explosion, with the loss of twenty-one lives. In 1848 similar accidents occurred in the French factories at Bouchet and Vincennes. The result was that its manufacture was prohibited and that the German Confederation refused to purchase the process. The inventors succeeded, however, in selling their secret to Austria and two plants were operated under the direction of an artillery officer, Baron von Lenk, until 1862 and 1865, respectively, when they also blew up and put a stop to further work there. Although Lenk had been extremely careful to purify his guncotton by washing for two weeks in water, boiling with soap and finally treating it with waterglass, his accidents as well as the previous ones in England and France were due to insufficient stabilization rather than from incomplete neutralization of the acids.

DIFFICULTIES CAUSED BY INSTABILITY

In the meantime an English chemist, Sir Frederic Abel, had come to the conclusion that the instability was due to traces of acid retained so tenaciously in the fine capillary of the cotton fiber that simple washing or neutralization with alkaline solutions did not completely eliminate them. In order to reach these traces of acid he broke up the fibers by pulping them in the beating engine of the paper industry. He also devised

a test, still known as the Abel heat test, for revealing the smallest traces of acid. Beating or pulping of the nitrocellulose is still practiced, although it is now realized that this does not remove all causes of instability, as will be shown later. In 1865, when Austria stopped manufacturing guncotton, England had two plants, one at Stowmarket and one at Waltham Abbey. The latter was under Abel's management and had in 1872 a production of 250 tons.

Aside from the troubles due to instability, there was another reason why guncotton did not immediately displace black powder as a propellant. It was too brisant—i.e., its rate of detonation was too great—and could not be sufficiently controlled, even by pressing it into solid blocks under heavy hydraulic pressure, to make it safe for use in rifle or cannon. Its chief military use was, therefore, as a charge for mines and torpedoes.

EARLY USES FOR NITROCELLULOSE

In the meantime nitrocellulose has found uses in the peaceful arts, and the developments here resulted later in serviceable nitrocellulose powders. Schönbein himself had observed that by varying the conditions of nitration he was able to obtain nitrocellulose insoluble, partly soluble or entirely soluble in a mixture of ether and alcohol. As early as 1848 Maynard made use of this solution in medicine under the name of collodion, which is still used as a dressing for wounds. In 1851 Scott Archer introduced the use of the same solution in photography. From that time on the use of nitrocellulose, or pyroxylin as it was generally called in the industry, increased rapidly as new solvents were discovered. In 1869 Hyatt obtained his patent covering the use of camphor as a latent solvent or plastifying agent for pyroxylin and thereby laid the foundation for the present enormous celluloid industry. It is true that Parkes and Spill had previously used camphor and camphor oil in nitrocellulose solutions to obtain a plastic film, but Hyatt depended on heat and pressure to develop the latent solvent powers of the camphor. Another extremely important patent is that of Stevens covering the use of amyl acetate, which inaugurated the lacquer and artificial leather industries that have since reached such huge proportions.

In working with these industrial plastics it was found that they burned with comparative slowness. This observation led the French chemist Vieille to the development of a completely gelatinized nitrocellulose powder in 1886. Nobel, who had invented dynamite, two years later (in 1888) patented smokeless powders consisting of nitroglycerine and nitrocellulose. From that time on these two types of nitrocellulose powders slowly but surely pushed black powder out of the place it had held in military affairs for centuries. In this

country, however, it was not until after the Spanish-American War that smokeless powder was finally adopted as the service propellant.

CHEMISTRY OF CELLULOSE AND NITROCELLULOSE

After this somewhat hasty review of the history of nitrocellulose we come to its chemistry. To be strictly accurate, it is not nitrocellulose at all, but cellulose nitrate. Furthermore, nitrocellulose, at least that found in regular practice, is not a definite compound, but a mixture of nitrocelluloses. This is due in part to the fact that the cellulose from which it is made is not a definite compound, but consists of a mixture of more or less mature or developed cellulose. Since both cellulose and nitrocellulose are colloids, whose properties gradually blend into those of the next higher or lower type, it is impossible to separate the different stages by crystallization and difficult if not impossible to separate them by fractional solution or precipitation.

We know very little about the structure or the size of the cellulose molecule. A number of structural formulas have been proposed, but none seems to correspond completely to the facts. The one proposed by Green is probably the most plausible:

Recent work by Pictet and Sarasin, published in *Comptes rendus* in 1918, promises to throw some light

FIG. 1. FEEDING THE COTTON INTO THE PICKERS PRIOR TO DRYING

on this question. They distilled cellulose under reduced pressure and obtained a crystalline product of the formula $\text{C}_6\text{H}_8\text{O}_5$ which forms a triacetate and a tribenzoate and may be the simple or unpolymerized mother substance of cellulose.

The usually accepted formula of nitrocellulose is $\text{C}_6\text{H}_{10-n}\text{O}_5 \cdot n(\text{ONO}_2)_n$ where n is 0 for cellulose and ranges from 1 to 12 for the different types of nitrocellulose. Those containing less than 7 $(\text{ONO}_2)_n$ groups are commercially unimportant. The most highly nitrated compound containing 14.16 per cent of nitrogen or 12 NO_2 groups has not been obtained, because the nitrating acid required for this stage begins to have a denitrating action before the nitration is com-

plete. Military guncotton (13.25 per cent of nitrogen) approaches most nearly to endeka-nitrocellulose, pyro-nitrocellulose (12.60 per cent of nitrogen) for the manufacture of United States smokeless powder corresponds to deka-, pyroxylin or soluble cotton for lacquers and dopes (12 per cent of nitrogen) to ennea-, and the nitrocellulose for plastics (11 per cent of nitrogen) corresponds to octonitrocellulose.

It is doubtful, however, whether any of these nitrocelluloses have ever been prepared in the pure state; certainly they have not in factory operations. A mixture of a number of them is always obtained, and the art consists in getting as uniform a product as is possible. As a matter of fact, the nitrogen content is not even a good indication of the suitability of a given nitrocellulose for any particular use. While it may be stated that a nitrogen content outside of certain limits will make the product unsuitable for a certain use, a product falling within these limits may be just as unsuitable. For instance, it is possible to make a nitrocellulose of 12.8 per cent nitrogen which is 95 per cent or more soluble in ether-alcohol solution, while another nitrocellulose of the same nitrogen content is less than 15 per cent soluble in this solvent. Nitrocellulose with less than 11.8 per cent or more than 12.3 per cent of nitrogen is generally unsuitable for gelatinizing nitroglycerine, but a nitrocellulose having 12.1 per cent of nitrogen may make just as "leaky" a gelatine. However, the nitrogen content has its importance and gives us valuable indications.

PROPERTIES OF NITROCELLULOSE

There are a great many solvents for nitrocellulose.¹ The commoner ones are the esters of the lower fatty acids and alcohols, acetone and other ketones, commercial wood alcohol (which contains acetone and other ketones), ether-alcohol mixtures, aromatic nitro-compounds, camphor and essential oils. Some of them will dissolve only certain types. Solubility in ether-alcohol mixture, for instance, forms the basis for the classification of nitrocellulose as soluble and insoluble nitro-cotton. The latter, containing generally more than 12.8 per cent nitrogen, is also known as guncotton. The former is often referred to as collodion cotton.

Nitrocellulose when ignited burns with great rapidity. It will take fire spontaneously when heated to a temperature of 186 deg. C., or lower, depending on its stability and the rate of heating. Even at ordinary temperatures it will lose nitrogen slowly, although very slowly if properly stabilized. This decomposition is a progressive one, the rate increasing if the products of decomposition are left in contact with it. For this reason stabilizers are added to smokeless powder which will bind the oxides of nitrogen as they are formed. The common stabilizer for pyro powders is diphenylamine. Vaseline, used in British cordite, oils, and various gums have similar properties. When gelatinized, nitrocellulose burns much more slowly. The combustion products vary with the pressure under which combustion takes place. In the open, oxides of nitrogen are always formed and a small carbonaceous residue remains. Under high pressures the combustion is more nearly perfect. It has been shown that a nitrocellulose containing 12.44 per cent of nitrogen should burn completely to carbon monoxide, nitrogen

¹See Worden, Edward C., "The Nitrocellulose Industry," New York, (1911).

and steam. On account, however, of a small amount of alcohol and stabilizer left in smokeless powder, its nitrogen content has been fixed at 12.6 per cent in order to insure practical smokelessness.

PREPARATION OF THE CELLULOSE

Cellulose is widely distributed in nature. Any of its various forms after proper preparation can be used, but in this country the usual raw material is linters obtained from the cotton seed after the best spinnable cotton has been removed. The great demand for powder during the World War would have made it necessary, if the war had continued another year, to use cellulose prepared from wood, such as the Germans had been doing since early in 1915. No matter what the source of cellulose, it has to undergo considerable preparation in order to make it suitable for nitration. Mechanical impurities have to be removed by dusting, and particles of seed, hull and the natural oils are taken out by boiling under a pressure of about 80 lb. in a 2 per cent solution of caustic soda. During this boiling care has to be taken to insure absence of air, which would cause the formation of oxy-cellulose and later give rise to nitrating troubles. After digestion the soda is carefully washed out and recovered. The cellulose next receives a mild bleaching treatment with bleaching powder, which is again completely removed, and the product is then dried. Chemical pulp made by the soda, sulphite or sulphate process is treated in the same manner and makes a satisfactory raw material for nitrating, especially when it can be mixed with linters, a mixture which is handled more easily than the short-fibered pulp. Wood pulp, however, is more bulky than linters and its use reduces the output.

When the bales of purified cellulose are received at the nitration plant they have to be opened up by being run through pickers. These machines consist either of drums that are studded with teeth or of corrugated circular plates rapidly revolving in opposite directions such as the Cogswell mill. The cellulose is then carefully dried from its natural 6 or 7 per cent of moisture to a content of less than 1 per cent. These preparatory operations are necessary in order that the cellulose will take up the nitrating acids readily and completely. Unopened lumps of cotton or high moisture would cause local overheating, uneven nitration and low yields.

The Government specifications for cellulose for nitrating prescribe an ash content of less than 0.8 per cent, ether soluble or fat content of less than 0.4 per cent, and no more than traces of salts of lime or bleach. Private manufacturers usually also place an upper limit on the allowable amount of oxy-cellulose as shown by the solubility in 10 per cent caustic soda solution.

EARLY METHODS OF MANUFACTURE

In the original process of nitration earthenware vessels were used that stood in iron troughs through which water circulated for cooling. Only 1 or 2 lb. of cotton was nitrated in each pot. After two or three hours the excess of acid was removed in a hand press and the nitrated cotton, still containing considerable acid, was permitted to stand in covered stoneware pots for twelve hours more to insure thorough nitration. At the end of that time the nitrocellulose was freed from more acid by centrifuging and then washed with water. This method was cumbersome and danger-

ous, since fuming off occurred quite frequently. The second nitration was soon abandoned and the cotton was left in the acid for twelve hours, after which it was centrifuged and submerged in water. As it was soon found that nitration, especially for the lower grades, could be carried on in a much shorter time, the pots were placed on turntables holding four or eight pots so that one pot after another would be brought up to the centrifugal and the process became a more or less continuous one—i.e., one man would dip cotton all the time and another would wring out the nitrated cellulose as the pot came up to the centrifugal. The

FIG. 2. AFTER THE MOISTURE CONTENT IS REDUCED TO 1 PER CENT THE DRIED COTTON IS WEIGHED INTO CONTAINERS AND SENT TO DIPPING POTS FOR NITRATION

next step was to carry on the nitration in the centrifugal itself. This arrangement is economical only where the time of nitration is quite short, as otherwise the ratio of output to investment would be too small. In order to provide a better and more uniform action of the acid, these nitrating centrifugals are often provided with a slow speed, which induces a slow circulation of the acid through the holes of the basket and back over the top of the cotton.

In the Thompson displacement system nitration is carried on in shallow earthenware pans provided with false bottoms and central outlet holes. The pan is filled with acid and the cotton immersed in it. A perforated plate is then laid over the cotton and cold water slowly run over the top. This water layer effectually seals the acid from contact with air and prevents loss of acid by fuming. After a certain length of time (one to one and one-half hours) more water is allowed to flow in and the acid is withdrawn at the same rate at the bottom of the pan until all of the acid has been displaced—a process which requires about one and one-half hours. This system is most economical in its consumption of acid, provided means are at hand for concentrating the weak acid formed during the last stage of displacement. It is not well adapted to the manufacture of soluble nitrocellulose on account of the difference in solubility between the different layers, since the bottom layer remains in contact with the acid almost twice as long as the top layer.

DESCRIPTION OF A MODERN INSTALLATION

The most modern system provides for the intimate and immediate mixing of acid and cotton in a different way. This system is installed in a four-story building. The top floor houses the motors for driving the machinery. On the next floor below four dipping pots for each unit, provided with agitators, are arranged in

the form of a square. These dipping pots discharge through valved pipes into the centrifugal on the second floor of the building. The centrifugal is discharged through its bottom into a bowl located on the ground floor. A stream of water entering this bowl tangentially submerges the nitrocellulose and carries it through a trap and earthenware flume to the boiling tubs, where the preliminary purification is carried on. The acid fumes, which were very objectionable in the old pot system, are sucked away by a fan from each dipping pot and each centrifugal. Occasionally there is a fume-off or "fire," which may be caused by foreign material in the cotton or a drop of oil or condensed moisture dropping into the centrifugal. In such a case the whole house is filled with fumes and the operators have to take refuge on the balconies that run the length of each floor. For these emergencies large exhaust fans with airplane propellers are provided, which clear the atmosphere in the course of a few minutes, thus confining the loss to the individual charge, whereas in the older systems often all the charges on the floor were lost, due to the inability of the workmen to return and attend to the work. The fumes coming regularly from the houses are conducted to absorption systems and recovered.

A charge consists of 1,600 to 1,700 lb. of acid and 32 lb. of dry cotton. The composition of the acids and the temperature of nitration depend on the type of nitrocellulose desired. In general it may be said that nitrogen content increases with increasing total acidity.

FIG. 3. CENTRIFUGAL SEPARATION OF NITRATING ACID

Increase in ratio of nitric to sulphuric acid, decrease in temperature and increase in time of nitration all increase the viscosity. The influence of nitrosyl-sulphuric acid or of the lower oxides of nitrogen is not thoroughly understood, but undoubtedly, other things being equal, increasing either lowers nitrogen content and viscosity. In addition the nitrosyl-sulphuric acid

FIG. 4. POACHERS IN WHICH FINAL PURIFICATION TAKES PLACE

has an oxydizing effect on the cellulose, resulting in compounds of low stability, which are destroyed during the purification treatment and hence lower the yield. Moisture in the cotton has a very serious effect on the product in that it dilutes the nitrating acid so that the interior of the fiber is nitrated to a lower degree than the exterior. This gives a non-uniform product, which will show itself in "granularity" or precipitation in the solutions. This, of course, is of less importance where the nitrocellulose is used for its flammable qualities, as in smokeless powder or guncotton, than where it is to be used as a solution, as in the lacquer industry.

BOILING PROCESS TO INCREASE STABILITY

It has previously been mentioned that the early troubles in the development of nitrocellulose were due to improper purification and that Abel introduced pulping to break up the fiber in such a way that the acid retained by capillarity might be completely removed. Even complete removal of acid does not, however, "stabilize" nitrocelluloses. This is due to the fact that the raw material is not pure mature cellulose, but always contains oxy- and hydro-celluloses in addition to less mature or complex cellulose molecules. The nitrates of these bodies as well as the lower nitrates and the sulphates of the pure cellulose which are always formed are unstable bodies. Fortunately they are rather easily broken up by boiling in acid water.

The first step in the purification is therefore prolonged boiling in water containing about 0.1 per cent of sulphuric acid. Extended experiments have shown that more than forty hours' boiling is unnecessary. The prescribed treatment for pyro-nitrocellulose intended for the manufacture of smokeless powder consists therefore of four boiling periods, the first one of sixteen, the other three of eight hours' duration each, with change of water after each boiling. The boiling tubs are generally equipped with a false bottom and a central stack or pipe into which the steam is introduced in order to provide circulation and even heating of the water, somewhat on the principle of the steam injector.

After the completion of the boiling the nitrocellulose is transferred to beaters or Jordans, where it is reduced to a fine pulp. These machines are well known to the paper industry and require no description. From the beaters the pulp is pumped to the poachers, which are simply large wooden tanks equipped with agitators. (See Fig. 4.) Here final purification takes place. As the principal purpose of this purification is the removal of the last traces of acid and the decomposition

products produced in the preliminary boiling, the requirements of the Army and Navy specifications seem somewhat excessive. These call for twelve hours' boiling with five changes of water—i.e., six periods of boiling followed by ten cold-water washings. During this boiling a small quantity of soda may be added. As a matter of fact, millions of pounds of smokeless powders which met all tests have been made from nitrocellulose that had only two periods of boiling (or a total of six hours) and five cold-water washings at this stage of the process.

OTHER METHODS OF PURIFICATION

The purification treatment described applies to nitrocellulose for making smokeless powder. For other purposes this can be much simplified. A great deal of nitrocellulose has been made and no doubt is still made for lacquers and dopes by washing only in warm water and dilute soda solutions. Some boiling should be given, however, but not too much, as excess of boiling has a bad effect on color and clearness of the solutions. Beating may be omitted entirely for this purpose.
